It is a grand achievement to have the means of locomotion brought to places which were so little time ago quite unknown and even non-existent. It is a great thing to have railways to the chair of the Bishop of London, and in 1816 he supplied the place of Guizot as lecturer on Modern History in the University of Paris. In 1815 appeared the work which first gained him a more than local celebrity, 'Histoire Critique de l'Établissement des Chemins de Fer dans la France Ancienne,' vol. 5vo. The following year he was made member of the Académie des Inscriptions, and one of the editors of the 'Journal des Savans;' and in 1816 he was appointed keeper of the medals, &c., in the Royal Library. His attention having been directed to modern Swiss history he, during the following years, took an active part in modern Swiss history he, during the following years, took numerous journeys in Switzerland, of which he published ample particulars under the title of 'Lettres sur la Suisse écrites en 1819-21,' 3 vols. 8vo, Paris, 1823-28, and 'Voyage Pittoresque dans la Vallée de Chamouni et autour du Mont Blanc,' 4to, 1826. His 'Histoire de la Révolution Helvétique de 1797 à 1803,' appeared in 1823. But whilst thus engaged on topography and modern history, he was still diligently prosecuting the study of classical antiquity, to which he had devoted himself. His journeys to Greece and Sicily, Italy, Germany, Holland, &c., in order to familiarise himself with particular localities and to examine the treasures collected in museums. In 1825 appeared his 'Antiquités Grecques du Boeotien et d'Olympos,' 4to. He had already come to be looked upon as the legitimate successor of Quatremère de Quincy, before the delivery of his lectures in 1826 on his appointment as professor of archaeology, which considerably added to his celebrity. These lectures were published under the title of 'Cours d'Archéologie,' and again in 1836.

From this time M. Raoul-Rochette was one of the most active and most widely known of the French writers on ancient art, communicating numerous papers to the Mémoires de l'Académie des Inscriptions, to the learned societies, and frequently appearing before the public in distinct works. In 1828 he published 'Monuments indéchiffrés figurés Grecques, Etrusques, et Romaines,'
RAUFS, CHRISTIAN, an eminent German sculptor, was born at Arolsen in the principality of Waldeck, on the 2d of January 1777. He early showed an aptness for art, and received instructions in it from the sculptor Professor Roth of Qurich, in Hesse. In the fourth year he was presented to an office in the court of the King of Prussia; but his spare hours were all devoted to art. He here secured the friendship of Count Sandrexy with whom he held a conversation as it were a tour through a part of France to Genoa, and thence to Rome. There with the advice and aid of William von Humboldt, then Prussian minister in that city, he devoted himself to the study of the antique, while he availed himself of the friendly instruction of the chief living sculptors, Canova and Thorwaldsen. After a due probation he produced several original works, among others, bassi-relievi of 'Hippolita and Phaedra,' a 'Mars and Venus' wounded by Diodames; a 'Child praying,' &c. But he began still more to distinguish himself in the line to which he had gone to give himself up. He executed portrait; besides abundant private patronage, he received from the King of Prussia commissions to execute a colossal bust of the King of Prussia, and a life-size bust of the queen; and a colossal statue of Caesar, &c. From a house in 1811 he was recalled to Berlin, to execute a monumental statue of the Queen Louise. His design was approved, and his health having failed, he was permitted to proceed to Carrara to complete the work, which he did in 1813, in a style that secured his reputation. He then went on to Rome, where he remained till 1822, when he returned to Berlin, where he afterwards resided. During his second residence in Rome, Ranch was chiefly engaged on busts and statues; he executed in marble, bronze, and terra cotta, the statues of the king himself, monumental statues of Generals Bulow and Schambhorst. By 1834 he had executed with his own hand seventy marble busts, twenty of them being of colossal size. Among the more important of his later works may be mentioned two colossal bronze statues of Field-Marshal Blucher; the first, representing the hero in vehement action, was erected with great solemnity at Breslau, July 9, 1837; the second, designed after Blucher's death, for the King of Prussia, represents the venerated monarch.

Another of his principal works is a seated bronze statue of Maximilian of Bavaria, erected in 1836 in Munich. The 'Victories' for the Walhalla, near Ratisbon, are also from his chisel. A well-known statue of Gótte, modelled from the fragments of a colossal statue in the Louvre by another sculptor, represents the great Bavarian empress. Statues in marble or bronze of Schiller, Schleiermacher, and others of his chief contemporaries, and of Luther, Albert Dürer, and other famous Germans of an older time, serve to show the high estimation in which his works are held by his countrymen; while bronze statues of two or three of the old Polish kings, which he executed for Count Raczyński, to be placed in Posen Cathedral, and a bas-relief erected at Dublin in memory of Miss Cooper, show that his ability was appreciated beyond Germany. The chief of his works is a colossal statue of Frederick the Great of Prussia, erected in the finest part of Berlin. This work, in the design of which Ranck was assisted by Professor Schinkel, the architect, and which called into exercise the resources of art, was executed in 1819 and 1822.

The general model was completed in 1839; the colossal model of the king was not however ready till 1842, and the statue was cast in 1846. Four more years were required for the execution of the bas-reliefs, and the statues of military commanders. The new palace of the prince, the Baron von Hardenberg, erected in the middle of the city, is, with the exception of the palace of Frederick the Great, the most imposing monument of modern art in Berlin.

Of this—perhaps the most elaborate monumental work of recent years—a small model may be seen in the Crystal Palace, Sydenham, as well as casts of the colossal equestrian statue of the king which crowns the monument, and which will be erected on the site of the old royal palace, on the first of August 1860, the anniversary of the battle of Jena and Auerstadt. The model is a copy of the statue of Frederick the Great sold to the city of Berlin in 1851. The original statue was ordered to be erected at Berlin in 1846. 

RAUPACH, ERNST BENJAMIN SALOMON, one of the most prolific of modern German dramatists, was born at the village of Sitzaupits, near Liegnits, in Silesia, on May 31, 1801. He resided for some time in Berlin, taking advantage of the political disunion of the state to visit the northern parts of Germany, and in 1801 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 1816 proceeded to Halle to study theology. He afterwards went to Russia, where for ten years he occupied himself diligently as a teacher, and after a residence, in that capacity at St. Petersburg for a year and a half, he was appointed professor of philosophy in the University of Liegnitz, and in 836 Proceedings of the Royal Society. &c.

RAZOR-BILL. [Aux.]

RECEPTACLE, in Botany, is that part of the flower or which any of the other organs rest. It represents the a
termed as the stem and branches in their changed position. It assumes a variety of forms, and occurs very variously into the forms of flowers and fruits. [CALATHEIDUM; FLOWERS, S. 2; FRUIT, S. 2.]

RED-BREAT. [ENTHICA, S. 2.]

RED BREAD. [ENTHIACA, S. 2.]

RED SANDSTONE. The term Red Sandstone is more especially applied to two formations, the Old Red Sandstone (Oreo Red-Sandstones, S. 2) and the New Red Sandstone Rocks. The latter are also sometimes called Silurian, on account of the salt they contain, and they are also called Triassic.

It is in Cheshire and the southern part of Lancashire, and the northern part of Yorkshire, which together form an extensive and rich plain, watered by the Dee, the Mersey, and the Severn. The red sandstones are chiefly developed; and by a minute examination of these beds, and those of Warwickshire, the Silurian marls have been identified with the uppermost series of the foreign Triassic System. Throughout this cave the beds are nearly horizontal, the dip rarely exceeding two or three degrees, and being constantly towards the east, or a few degrees south or south of that point. They are, however, affected by some important faults. The whole district is covered generally by a mantle of clay, which is especially thick in Cheshire; and in that county also there occur extensive masses of rock-salt in a solid state, their total thickness amounting to not less than sixty feet. These alternate with beds of gypsum; with numerous bands of indurated sandstone and sandstone and sandstones, frequently marly, and of a red colour.

The red-marl district, with brine springs, is continued northward into Worcestershire, and northward into the valley of the Thames. The part of the formation extending also eastwards, occupying for the most part the plains through which the Humber and its tributaries make their way to the German Ocean. In Somersetshire and Devonshire similar sandstones occur, and lie unconformably, over-lapping the same, which must have been submerged against them, but uniformly composed of the same materials, remarkable throughout for the ochreous colour pervading them. Between Sidmouthe and Seaton, in Devonshire, the red marls contain gypsum in abundance; and near Teignmouth the cliffs, which are of considerable height, consist of alternations of argilloaceous beds of sandstone and conglomerate.

The beds which are lowest in position of the upper red sandstone, are chiefly found in the middle of England, and consist of thick masses of whitish soft sandstone. In some places (as in Staffordshire) these are surmounted by conglomerates, composed of rounded pebbles of quartz rocks, and other fragments, chiefly of Silurian rocks and old red-sandstones. The thickness of the formation is considerable, but has not been accurately calculated. It is only to be distinguished from the overlying silurian marls by small differences of mineral character. (Annot.)

The red sandstone system of rocks is one of the most varied and interesting we are acquainted with. There are peculiarities in its limestones, sandstones, and clays, as well as in its gypseous and salt deposits; the occurrence and nature of its organic contents, and the relation which it bears to other earlier and later classes of rocks, are worthy of careful study.

Sulphate of lime is found perhaps as frequently, and under almost as many curious circumstances in the stratiﬁed rocks, as carbonate of lime, in molasses aggregations, occasional prismatic prisms of calcite, and even as with the娟 (selinite), fibrous masses, and bands, and marmoloid or alabasterine rocks. It lies in strata of almost every age, and is not absent from diluvial, alluvial, and recent deposits. The mode of its occurrence is in a considerable degree analogous to that of the mineral itself. While long prismatic crystals appear in cavities of shells and in recent excavations (as in the gallery of Felling Colliery, Newcastle), the solitary broad ﬂaky crystals of selinite abounded in blue-clays of the tertiary and second period. The long prisms of iron, and the ﬂat gypseous marks, spots, and irregular lines in the red-clays (coloured by peroxide) of the Silurian System, the ﬁbres being (in agreement with a general law of structure) arranged so as to render them able to wound round the mass. The marmoloid texture is most commonly found in real however irregular beds, as at Moutounart, and is some points near Fairburn in Yorkshire, on the line of the York and North-Midland railway. At these places, ﬁbrous, marmoloid, and ﬂaky sulphate of lime may be obtained in association.

From what is known to take place at the present day, and from appearances in the distribution of the gyspum and selinite in masses of clay and cavities of shells, &c., it appears that the red sandstones have been at different periods subject to evaporation and may have given rise to deposits of rock-salt at various points. This has been shown to be the case at Peine, and at Teignmouth, and has probably been the case generally, particularly when the red-sandstones were subject to the action of salt solutions. The occurrence presents no particular difficulty.

Salt shows itself in the Cheshire mines as either granular, broadly laminated, or ﬁbrous; in great beds or minutely mixed with marls, nearly as gyspum is, and probably in regard to its origin, similar suppositions will apply, the solid beds (of limited extent, however, and irregular area) being due to a great evaporation of liquid over the previously deposited salts. That such water, in the case of rock-salt beds, is of organic nature, has been proved by the existence of organic remains in the new red-sandstones. The original masses during crystallisation presents no particular difficulty.

We ﬁnd, then, associated together, abundance of red-oxide of iron, salt, and gypsum, but few or no organic remains. The prevalence of red-oxide of iron in any of the strata is accompanied by a paucity or total absence of organic remains. In the new red-sandstones these red strata extend through several hundred feet of thickness, and it is found in general terms, that the types of organic life above and below are widely different. Similarly the thick series of old red-sandstones, which are divisible into two distinct groups of these productions. Some great physical changes must be supposed to have occurred previous to and during the saliferous period, and to have inﬂuenced both chemical and physical phenomena.

M. A. von Brongniart ("Prodrome d'une Histoire des Végétaux Fossiles," 1829), viewing the series of fossil plants, gives four great periods of ancient vegetation:—The ﬁrst extending from the earliest strata to the new red-sandstone strata; the second including these strata; the third including the ooliths and chalk; the fourth the tertiary strata. Of these the ﬂora of the second period (chiefly terrestrial) is very limited, and may be looked upon as a transition group of plants connecting the earlier and later periods. Similarly the series of marine foraminiferae which lie in the new red-sandstones have characters intermediate between the early (Paleozoic) and later races of pre-adamite life.

Although the fossils of this rock are but few, they are highly interesting. In amongst these rocks that we ﬁnd the ﬁrst traces of reptile industry, the ﬁrst chelonians, which was at ﬁrst called Chirotherium, is now known under the name of Labirynthodon. It belongs to the amphibious tribe of Reptiles. Footmarks of an extinct reptile have also been found in the red-sandstones of America, and described by Dr. Lea.

The equivalents of the British beds of new red-sandstone on the continent of Europe are—the Kamper Marls, or Marres Irrities, the Muschelkalk, and the Bunter Sandstein, or Grès Triasique, of France.
insurrection broke out in the Morea, Redschid served in the campaign under his patron. After the defeat of Pashas Ali, the Emperor of Soliman, he was made the private secretary in 1832. He now began his preparation for the higher offices of state by a series of foreign missions. In 1831 he was sent as envoy to Mehemet Ali, viceroy of Egypt, with the exception of a visit to the Christian and Jewish communities; and in 1833, he was in the following year raised to the dignity of Pasha. In the course of 1834 he was sent on a mission to the courts of London and Paris. Nearly two years were thus occupied, and the relations he formed with the English and French were so cordial that during his absence in England and France, became the basis of the credit and influence he obtained on his return to his native country. The great measure of Parliamentary Reform had recently become one of the most pressing objects of the government, and the subject was still fresh in men's minds. Redschid Pasha was particularly impressed with this great change, affected as it had been without reconces to violence. When he was recalled to his own court, the following year, to fill an important office in the administration of Pestier Pasha, his mind was occupied with the subject. Almost immediately after his arrival he found himself exposed to imminent danger by the death of the prime minister, who had been thrown over by an intrigue within the palace, and his downfall was increased by an attempt on his life. Each of his behaviour of Redschid Pasha was so circumspect as to baffie the designs of his enemies; whilst the credit he had obtained from his diplomatic missions was so high that he was created Grand Vizir in 1837. He did not however hold this position long. In the formation of his cabinet, Pestier Pasha, was passed to a Foreign Minister, and the practical knowledge and statesmanship which he had acquired in his European missions, are attributed to the systematic reforms which, under the name of the 'twenty years' have distinguished the reign of the present Sultan. Indeed, it is generally believed that from the accession of the young monarch in 1839 until the end of 1857, a period of nearly nineteen years, Redschid Pasha steadily pursued his object of introducing political reforms into Turkey, and that to him is mainly due the many great—however imperfect—social and religious as well as political improvements which have been effected in that country. But it was amidst much hostility and discontent that Redschid Pasha prosecuted his system of reform. In the late war with Russia he was called to direct the government, which through that difficult period he accomplished with signal ability. Though afterwards for a time displaced, he again became the actual head of the Turkish government, and the period during which he was in power produced to the statesmen gave him a strong hold on power. In private life he likewise, by example as well as otherwise, sought to modify the objectionable habits of his countrymen: he had but one wife; and he was said to have freed the corrupt practices commonly attributed to the higher official classes. He died on the 7th of January, 1855.

REFORMATORS. The establishment of new and the extension of existing Reformatory Schools have been provided for by the statute 20 & 21 Vict. c. 65; the previous statute 17 & 18 Vict. c. 36 having only provided for young criminals being sent to the schools which had theretofore been estab-

REGULUS. [Cockatrice.]

REGULUS, a genus of Birds belonging to the family Sylvidae. The genus is thus defined by Mr. Yarrell—Beak slender, straight, the edges dilated at the base, compressed towards the point; nostrils basal, lateral, oval, partly covered by small feathers directed forwards. Wings of moderate length; the first quill-feather very short; the second almost as long as the third, but the fourth much of the longest in the wing. Legs rather slender; feet short; toes four, the middle one and the outer toe joined at its base to the middle toe; claws curved and sharp. This is a three British species of the genus.

R. modestus, the Dalmatian Regular. This is a very rare species.

There are three other species natives of North America.

REMORA. [Echeneis, s. 2.]

RENDELL, JAMES MEADOWS, a civil engineer of great eminence, was born in 1799, at a village on the borders of Dartmouth, in Devonshire. His father, Mr. Meadows, was a well-known architect, and his father, who was a man of ability, excellent common sense, and determination of character, qualities which de}-

R. modius, the Fire-Crested Regular, Fire-Crested Wren.

[Phraomitb.]

The young Mr. Rendel was employed on the survey and experiments for the proposed Suspension bridge over the Mersey at Man-

R. igniculus, the Fire-Crested Regular, Fire-Crested Warbler, or Kinglet.

This bridge, consisting of five elliptical arches, was, with the exception of that of Southwark, the largest cast-iron structure of the kind in the kingdom. Mr. Rendel was engaged in its construc-

tion from 1824 to 1837. For his account of this work he was awarded the Telford medal of the Institution of Civil Engineers. A description of the structure of these bridges, as well as of that over the Lary, was published in the Institution of Civil Engineers. The construction of the latter were also communicated by Mr. Rendel, in 1859, to the Plymouth Institution, of which he was a member, and pub-

lished in the following year in the only volume that has hitherto appeared of its 'Transactions.'

The repairs of the Montrose suspension bridge, after its fall, were confided to him, and he there introduced the system of importing that rigidity to the platform of the roadway which is now considered the essential part of such bridges. In 1833 Mr. Rendel removed to London, where he was soon consulted upon many important works, and was engaged in the chief parliamentary contests of that remarkable period in the history of engineering. About this time he designed the pier at Millbay, and he introduced the system of con-

struktion since employed with so much success at the harbours of Holyhead and Portland. Engagements promised in fast upon him, and his career was for the next few years one of quick succession of projects for docks and harbours, for wharves and docks, and the improvement of rivers and estuaries. In the year 1843, the projected construction of docks at Birken-}

head, in Cheshire, of such an extent as to create a formidable rival to Liverpool, brought him very prominently before the attention of the most important political institutions. He will long remembered in the history of parliamentary committees, for the ability with which he defended his positions; and the evidence given by him and other engineers, as now
collected, forms a valuable record of the state of engineering practice. The almost incessant labour, and the mental anxiety inseparable from this undertaking, were more than enough to exhaust his resources, and to exhaust support, and it is feared that they tended to shorten his life.

The daring project of constructing a dock at Great Grimsby, by projecting the works far out upon the mud-banks of the Humber, was next successfully accomplished; and he commenced the invaluable work which was to forge down his name to posterity besides those of Smeaton, Rennie, and Telford,—the harbours of refuge of Holyhead and Portland. Both these works were conceived with the largest views, and have been carried on with rapidity. In both cases the system was adopted of establishing timber stages over the line of the jettys and depositing the large and small stones together, as they came from the quarries, by dropping them vertically from railway wagons into their positions, thus being able to advance the work at a rapid pace. These two great works are advancing very satisfactorily; and it is worthy of remark, in evidence of the engineer's sagacity in the adoption of this system, although the severest storms which have repeatedly occurred on the exposed coasts where they are situated, have done some injury to portions of the stages, and of the temporary works, at Holyhead—where the piles were not shot with Mitchell's screws, which proved so successful at Portland—not a stone would appear to be dislodged, and the success of the system may be said to be complete, in spite of the sinister predictions which prevailed before it was tried. Among the other works upon which Mr. Rendel was engaged, should also be mentioned the constructions on the River Lea, and on the Chichester and the Arun canals. The former was employed by the Exchequer Loan Commissioners to report upon the drainage and other public works in Ireland.

He was less engaged in railways than hydraulic works; but in England he executed the Birkenhead, Lancashire, and Chichester Junction Line, and he had the direction of the 'East Indian' and the 'Madras' railways in India, the former projected by Mr. (now Sir Rowland) Macdonald Stevenson, as the first of the vast system now in progress, which on its completion will give to that country, the destined of our Indian Empire. The Ceylon line and that of Pernambuco in Brazil were also under his charge.

There was scarcely a harbour or a river of importance in the kingdom with which Mr. Rendel was not connected in some capacity. His advice was also sought by foreign countries; and he was engaged to report upon works for the Brazilian, the Prussian, and the Sardinian governments, and was nominated by the Viceroy of Egypt a member of the Imperial Egyptian Institution. The first step towards the construction of the proposed canal across the Isthmus of Suez.

In consequence of the danger which threatens the port, and therefore the city and republic, of Hamburg with ruin, from the rapid accumulation of sand in the bed of the Elbe, the navigation of that river was seriously interfered with, and the navigation of that river, and make proposals for averting the danger. A commission of such importance could not have been intrusted to more able hands. He spent some months in studying on the spot the nature of the difficulties to be overcome. Towards the end of the year he sent in a most able report, with a detailed account of his plan for remedying the navigation, and preventing any future recurrence of the deposit of sand and formation of a bar in the river. The report was printed and laid before the Bürgerschaft, or representative body of the citizens, but down to a very recent period the requisite works had not been commenced, or even determined upon, notwithstanding the rapid increase of the evil. Mr. Rendel proposed to construct a longitudinal dam or dyke in the middle of the Elbe, beginning at the island of Finkenwerder, a few miles below Hamburg, and extending down the stream for a distance of nearly forty miles. This would contract the main body of the river, and prevent the sand from spreading on the lower channel. The rush of the ebb and flood tides would not only sweep away the present sand-banks and other existing obstacles, but prevent them from ever forming again, deepen the channel, and canals, and increase the capacity of the water of the Elbe, allotted for the execution of this great work was seven years, and his estimate of the expense amounted to 8,800,000l.

In the words of the Proceedings of the Royal Society, from which, with some omissions and corrections, the present article is principally, though not wholly, derived, the subject of it "was a man of great energy, clear perception, and correct judgment; his practical knowledge was well directed, and he knew how to make good use of the scientific acquirements and skill of all whose services he engaged. His evidence to the committees was lucid and convincing, seldom failing in carrying the point. His reports on engineering works are distinguished by the clearness and correctness of his views, and the fearless expression of his opinion."

Mr. Rendel was a very early member of the Institution of Civil Engineers, having joined it in 1834. His professional character, administrative ability, and scientific knowledge, conspired to give him a seat in the council as Member and as Vice-President for the sixteen years preceding his death; and he was elected president in 1858.

He also became a Fellow of the Royal Society on the 23rd of February 1843; and, accordingly to the system which has of late prevailed of adding to the representatives of science in the council of the Royal Society of the English undertakings, during the years for which he was president of the Institution of Civil Engineers, he was also chosen upon the council of the Royal Society. Mr. Rendel was as amiable and kind in private life as he was energetic and firm in public, and his decease, which occurred on the 21st of November 1856, cast a gloom over the whole of the profession of which he was a brilliant ornament.

REPLEVIN. The proceedings in a replevin have been generally deemed the most summary of all the civil actions; and are perhaps the most widely used form of proceeding in our law for the preservation of rights. It may be most conveniently described by assuming a case under it, where a landlord is concerned, by the statute 19 & 20 Vict. c. 105. Replevins were previously granted by the sheriff's deputies; they are now effected by the registrars of the county courts. A bond is taken, as formerly, that the replevior shall bring an action within the time for the recovery of the property, or the court may decide for the landlord. The court may order the defendant to remove the cause from the tenant, but to lose his cause unless he proves that the title in dispute, or the rent or damage in respect of which the distress was taken exceeded 30l, in value. The statute is confined to replevins of distresses taken for rent, rentar or damage feasant; but the restriction is practically needless, for the other species of distresses known to the law have long been almost entirely obsolete.

REPRODUCTION OF PLANTS AND ANIMALS. The term Reproduction has been employed to denote those processes in organic beings by which the individual being is produced, developed, and maintained. It has thus been employed to express processes which are functionally distinct, and have very different ends in the economy of creation. The constant reproduction of the same tissues in the same part, is the means by which the form of the individual being is maintained during its life, and is the result of the ordinary processes of growth. The reproduction of all the species, or of the whole of the vegetable kingdom, the whole animal kingdom, or the whole of the being occurs. The power, however, of reproducing the same tissues, varies in different beings, and we find that although it is possessed even to the most insignificant individuals, the lower animals, no such power is possessed by the highest.

The term Reproduction has also been applied to the origination of the germ from which individual plants and animals grow. The process employed in the initiation of life seems to be essentially distinct from those engaged in carrying it on: hence the propriety of distinguishing in terms between that production of cells by which the life of the individual is maintained, and the arrangements by which its existence is prolonged to an individual. It has been proposed to restrict the term Generation to the latter process.

Although formerly great difficulties existed in distinguishing between these two processes from the want of sufficient observations, recent researches have allayed all that is necessary. In the ordinary reproduction of the tissues of plants and animals each cell has the power of producing other cells, or a large number of the same kind of cells are developed simultaneously, but in generation it is necessary that two cells come together. It is supposed that this process did not take place in the generation of the lower animals and plants, but recent investigations have shown that the natures of two cells is necessary to so produce a number of the lower plants and animals, that it is a fair inference that this process is distinct in the generation of organic beings. The two cells thus engaged have been called the germ-cell and the sperm-cell. The germ-cell is that in which the process of growth of the new being commences, while the sperm-cell which communicates the growing tendency to the other. These cells
are of different sizes and forms in the animal and vegetable kingdoms, and are placed in various positions in relation to one another in the same structure. But these characters are of necessity to be understood as indicating the action of some force which is very complex in its nature, and may be best comprehended by the use of the expression 'equivoc.' or 'spontaneous generation.'

The discovery of the necessity of the union of these two cells, for the production of a new being, has gone far to settle the question of 'equivoc.' or 'spontaneous generation.' Ever since the extended use of the microscope in the investigation of the structure of the organic beings, it has become more and more apparent that there was no basis for the supposed independent spontaneous generation of a preceding organism. The only cases in which it is now pretended that such an origin of organic life could take place, are those in which the minor forms of animal and vegetable life occur in insuffusions exposed to the atmosphere. But this occurs only in explaining the production of a new being, it is remarkable how exceedingly minute many of these organisms are, and that they are frequently produced from ova much smaller than themselves. Such organisms are easily taken up into the atmosphere, and can be thus conveyed from one spot to another. Such is the fact proved by the experiment of passing atmospheric air through red hot tubes or strong sulphuric acid, when it is found that water exposed to such air never affords any indications of the existence of organic beings. But water exposed to atmospheric air will, in a few hours, teem with living beings.

Although the subject of the generation of animals and plants has been regarded as a subject of much mystery, the facts which I have stated as well as others; have given rise to a branch of physiological inquiry. The greatest mystery is the mystery of all nature, and that is the reason of the assumption of a particular form by what appears to be the same combination of elements. No difference can be discerned between the cells of the Fowls of the same species, the oak and the apple, but the one always produce oak-trees, whilst the others always produce apple-trees. It is the same with the cells of animals, without the slightest appreciable external difference; but one set of cells will develop the form of one species of animal, and another set of another species; in this fact has led some inquirers to the assumption of the existence of a 'vital principle,' of a distinct and independent essence, giving to each species its definite form and character. There is no objection to such an hypothesis, provided it is not made use of to explain phenomena which are clearly under the influence of chemical and physical forces. As so much misunderstanding prevails with regard to the word 'vital principle,' it is better perhaps to discard it, and to speak of the limits of each species, and of each species of another species, under the control of a 'formative force.' This formative force being the ultimate fact in the history of each individual plant and animal, and regulating the chemical and physical processes, is usually called life, it has been proposed to call this a germ-force, or a germinal capacity; but as it is very clear that it is the same force that is in action to produce the whole life or growth of the plant or animal, there is no necessity for distinguishing its first effects, as observed in the act of generation.

In studying, then, the phenomena of generation, there are three conditions which have to be regarded.

Firstly, the Formative Force, which is peculiar in every species, and identical in all the generative cells produced in that species.

Secondly, the Physical Conditions in which the generative cells are placed. These are more especially heat and light, and the condition of the cell-membrane through which always passes a number of other forces.

Thirdly, the Elements which are supplied for the nourishment of the new being, and which by their Chemical Properties are capable of exercising an influence on the form and development of the plant or animal.

Each of these conditions is fixed exercising varying degrees of influence in plants and animals. Thus, amongst the lower forms of both the animal and vegetable kingdom, the formative force appears to exercise less influence than amongst the higher forms. This is seen in the difference of the same species of plant and animal assume under different circumstances. In fact, till very recently, many of the forms of Fungi, Algae, and Infusorial Animals, which had received different generic names, are now found to belong to the same species, and are produced as a kind of degenerate condition, produced by the influence of the third set of circumstances. The highest animals and plants are however liable to great modifications of the activity of the formative force by the operation of both physical and chemical circumstances. Loss of heat, the action of water, the exclusion of air, and the change of external temperature take place. Plants will not produce their leaves without the influence of light. Tadpoles are not developed into frogs and toads when deprived of light and heat. The disappearance of the green color in plants, the withering away of the flower, the decay of the animal is occasioned by the change of its food. The Brachiostoma of the sea-shore is converted into red and white cabbages, cauliflowers, and broccoli, by garden culture. All cultivated plants exhibit more or less modification of their growth under the influence of physiologic forces. The horse, the sheep, and himself, present varieties which, are manifestly dependent on external circumstances, and not on any change in the character of the formative or species-making force.

That there is no change in the character of this force is seen in the tendency which all the forms of a particular species have to revert to a definite type, or to cease to exist. This is seen especially in the case of cultivated plants and domesticated animals, which are subject to the greatest varieties of form, but which nevertheless retain through all, the evidence of a specific formative force. Thus, closely allied as are the species of apple and pear (the Pyrus malus and Pyrus pumila of botanists), and subject as they are to the same external influences, the apple has long been produced in Great Britain alone, there is not the slightest tendency in any of these cases towards confusing the specific character of the apple-tree and the pear-tree. Although we have seen that any number of species can even breed together, but the hybrid is not prolific, and there is no tendency on the part of the one species to degrade or develop into the other. All the facts that are known with regard to the nature of the formative force lead to the conclusion that it is one and the same, and not general, and that it is regulated by the same laws throughout all time.

In what is called the alternation of generations [Generation, Alternation of, S. 3], it might be supposed that an exception occurred to the ordinary process of generation. It will be seen, however, that the cases in which this phenomenon occurs, it results from modifications of the ordinary processes of reproduction, and the unusual disposition of the sperm-cells and germ-cells.

Having made these general remarks, we shall now proceed to speak more particularly of the process of generation as it occurs in plants and animals, restricting this term to the phenomena which take place as the result of the union of two cells. That reproduction in plants which occurs as the result of the growth of the same tissue from single cells, when it results in the production of a bud, is termed Gemmation or Sprouting. This kind of reproduction also takes place in the animal kingdom, and amongst many of the lower animals, there is no difficulty in the process of budding is seen. To this process of forming new beings as it were, from single cells, Professor Braun of Berlin has applied the term 'Verjungung,' which has been translated by Mr. Herford 'rejuvenescence.'

Amongst plants the lowest position must be assigned to the families Diatomeae and Desmidieae, and it is amongst these that the most clear evidence has been obtained of the union of cells in order to the production of the zoospores from which the new being is developed. (Diatomaceae, S. 2; Diatomaceae, S. 3.) The union of two cells is also seen in a large number of Conformae, especially in the groups to which the Zygoplanea belong. (Zyzoplanea.)

Although amongst the Algae the production of spores can be traced to a certain number of species, between two cells, their multiplication more ordinarily takes place by means of zoospores or zoosporoid bodies, which are perfectly homologous with the buds or sprouts of the higher forms of plants.

In the Fungi we meet with a variety of reproductive organs. As these have been investigated very recently, we give the following extract from Dr. Sanderson's account of the vegetable ovum in the 'Cyclopedia of Anatomy and Physiology.'

The simplest form of reproductive organs in the Fungi are those in which the species occurs on a basis or baimium.

The right use of the term 'individual' in Natural History is a difficulty. If the term is restricted only to the direct produce of the germ-cell and not to any intermediate stage, it can hardly be objected to. If, on the contrary, it is understood to include the entire process of reproduction, and the different reproduction of the germ-cell, its use in natural history becomes a matter of doubt. In order to confine the term individual to such cases, it has been proposed to give the term 'spore' or 'zoospore' to the independent structures which result from spore-producing, germination, or spore spread.
This form of organ is best seen in Greater. The next form of reproductive organs in the *Fungi* is in the form of a vesicle or bag, which is called a theca, or ascus. "Of these, the first which we shall mention belong to a group of subter- ranean plants, of which the Truffle is the best known example. The receptacle of the *Fungi* consists of a fleshy mass, throughout which numerous sinuous cavities are interpersed. Each cavity is partly lined, partly filled with the theca and the cells upon which they are supported. This receptacle, like that of all other *Fungi* with which we are acquainted, consists of a number of separate cells which close together; and when it is in the form of a whitish mass, so that on section, we observe the whole to consist of two substances—the one transparent, of firm consistence, and of a dark-brown colour; the other white and opaque. The former, which corresponds to the partitions which, in the young state of the Truffle, separated the cavities, is continuous with the external tissue which composes the envelope or peridium, and constitutes the venas interna of Vittadini. The laminae which it forms consist of filaments running for the most part, parallel to each other. The central column being formed by the tube of the theca, which is composed of the tubular cells, which are given off in great numbers from the surfaces of the laminae. These tubes, which are the terminations of the filaments of which the laminae are composed, have a circular or oval diameter throughout, and divided at intervals by septa; others much shorter are dilated at their extremities, and contain spores (thecae). Each theca is an oblong vesicle, and contains two, three, or more spores, never more than eight spores, and these are produced, as it were, in the same, or sometimes warty epispshe, within which may be distinguished a smooth inner membrane, immediately enclosing the oogogenous contents.

The receptacles of *Fungi* are represented in their simplest form by the *Uredinae*, a family which has been studied by numerous observers on account of the destructive properties of the plants belonging to it. The mass which is formed by the growth of the reproductive organs of *Uredo* under the epidermis of the leaves of the plants upon which it grows or sometimes warty epispshe, within which may be distinguished a smooth inner membrane, immediately enclosing the oogogenous contents.

The next *Fungi* are the *Uredinae*, a family which has been studied by numerous observers on account of the destructive properties of the plants belonging to it. The mass which is formed by the growth of the reproductive organs of *Uredo* under the epidermis of the leaves of the plants upon which it grows or sometimes warty epispshe, within which may be distinguished a smooth inner membrane, immediately enclosing the oogogenous contents.

They are probably the enlarged extremities of the mycelium filaments, with which many of them can be distinctly traced to be connected. Towards the base of the cavity, the outer wall is produced and thickened, as mentioned in their general form, as well as in their relation to the mycelium. In these however the membrane is produced inferiorly, so as to form a tubular pedicle; while in the club-shaped upper extremity it is lined by a considerable deposit of granular protoplast, so that here the mycelium is very much smaller than that of the external membrane. It is in this cavity that the spores are formed, at first not exceeding it in size, but afterwards increasing at the expense of the protoplasm, so as almost to fill the theca. In other genera, as in *Peronosporae*, the protoplasts are pedicellated cells of a similar form and originating in a similar manner, which, however, instead of one spore, develop another in their interior; these spores are arranged in linear series, and are formed in a single cap, which appears completely, but remains as a more or less consistent membrane, giving the spore to the spore-case which encloses it. Some of the *Uredinae* possess a cyst which remains as the peribacterium of the *Sphaeriae*, to which these are evidently closely related. The cyst is formed (Celidium) of a single layer of roundish cells.

From the *Uredinae* we pass by a natural transition to the *Discomycetes* and *Pyrenomycetes*. These plants have been investigated by Messrs. Fries and Sprengel, who have shown that they possess the closest relationship not only to the Lichens but to the most simple thread *Fungi*. The very remarkable facts which these observers have discovered, render the study of these plants more satisfactory and interesting. They have described a series of *Sphaeriae*, which are sometimes cysts, and which enclose the spores. The *Pyrenomycetes* are represented by *Sphaeria*, the receptacle of which consists, as is well known, of a spherical cyst, which is open above. Its wall is frequently prolonged

upwards into a tabular beak, which projects beyond the surface of the bark or wood in which the whole plant is imbedded. The membrane of the cyst (peribacterium) is usually composed of polygonal tabular cells; it is lined by an inner layer, formed of the commencement of the paraphyses and the stellate spores, and is generally connected. The theca are oblate cells, and the membrane of which is of extreme delicacy. When fully formed, they contain from three to eight oval spores, the episphe of which are in the early condition delicate and pallid, but by degrees become more or less pigmented; the outer portion, as is observed throughout the higher *Fungi*, consists of fluid loaded with oily granules. The spores are arranged with their long axes perpendicular to the inner surface of the theca, and are enclosed in the operculum, and are separated, instead of a larger number of algal cylindrical paraphyses. The whole peribacterium is usually enveloped in the filamentous stroma or mycelium, from which it takes its origin. The *Discomycetes* are represented by the *Pezicse*; between these and the *Sphaeriae* there are differences of external form, which, though they strike the superficial observer as important, are in reality trivial. While the receptacle of the *Sphaeria* is a cyst with an apical aperture, that of the *Pezicse* is a cup-shaped disc, the concave surface of which efforts upward, terminating in a cysl, the internal diameter of which is completely, or nearly so, surrounded by the external theca, which resembles in every respect that of a *Sphaeria*.

Along with the *Pezicse* and *Sphaeriae*, and those allied genera which resemble them in producing their spores in clusters, and which we may call *Pyrenomycetes*, are the *Discomycetes*, which, while they resemble those last named in the general outline and structure of their receptacles, differ from them completely in the mode of origin of the spores. The simultaneous occurrence of some of these genera along with their respective allomorphic analogues, or, in other instances, the successive development of both kinds of receptacles in the same position, had been frequently observed, and had given rise in the minds of some mycologists to the idea that the relation more close than was generally admitted. This suspicion did not, however, take a sufficiently distinct form to lead to observation, until the Messrs. Tulane, in a series of researches scarcely completed, showed that the genera in question, hitherto considered as distinct, were in fact identical, and that receptacles containing thecae and paraphyses, are produced on the same stroma, or, in other words, on the same individual plant, as those which contain aerogenous spores.

The earliest researches of Messrs. Tulane were directed to the *Pyrenomycetes*. In some species of *Sphaeria*, they found not only that the same stroma produces receptacles with aerogenous spores, which is followed by others bearing a member of a very different order of the plant, but occasionally to a stroma which is capable of rising to spore-bearing organs of a much simpler character; namely, branching filamentous pedicels, bearing at their terminations single spores, and rising directly from the mycelium filaments, with which they are continuous. In this condition the plant cannot be distinguished from a thread fungus, and has been hitherto described as such.

"The later observations of Messrs. Tulane, which are much more in detail, refer almost entirely to *Discomycetes*. In a species of *Rhizina*, a genus of *Discomycetes*, which inhabits the epidermis of many plants, the stroma at first presents the appearance of a black spot of various extent on the surface of the leaf. In the substance of this stroma the first receptacles are formed; they are cushion-like, as they grow, and are gradually connected with each other to form a number. As this process continues, the membranous thecae, and are entirely occupied by a pulpy nucleus, which consists of slender branched filaments, often so long as to project considerably beyond the apertures. These filaments bear at their extremities innumerable minute linear spores, which are enclosed in a abundant mucilage, and are expelled from the ripe capsules in the form of a long cirrhus. After the capsules, which are developed during the early summer months, have discharged their spores, the *Rhizina* is reduced to a perfect *Rhizina*. These do not arrive at maturity until the following spring, and bear upon their upper surface thecae and paraphyses, like those of a *Pezicse*. In other genera M. Tulane found that the ascohosphorous receptacles are covered by a sort of membrane, and that the spores described above mentioned, cylindrical spores of a much larger size, each of which is supported at the extremity of a pedicle of its own.
Thus in the plants under consideration we find that, without counting the organs produced by filaments, as directly from the stroma, there are no less than three varieties of spore-like structures, which can be easily distinguished from each other. All of these may be produced upon the same individual, and one is recorded in which all three varieties exist, and forms the normal theca, paraplasthies with innumerable slender linear spores at their extremities. As has been already hinted, the capsules which contain acrogenous spores, have been hitherto considered as belonging to genera distinct from those of the sperm-cells; and recent researches with which they were found associated. The genus Stypopora is characterised by a structure which completely with that of the capsules described above in Rhizomea, and other genera with similar relations, as being a sort of extension to the capsules, containing the larger variety of pedunculated cylindrical spores.

We know less of the reproductive organs of the Lichens, but they however closely resemble those of the Fungi. The following is a summary of the reproductive organs found in these two orders:—1. Sporules which are formed by the constitution and separation of the extremity of a simple cylindrical filament. 2. Spermatia, with their supporting pedicles. 3. Gametes (given to the style) Thecia, or ascus, and Basidia, with their suspensoria. Although the evidence is as yet imperfect, there is still good reason for supposing that the ascii and spermata are truly sperm-cells and germ-cells, whilst the other organs represent the germs or buds.

The reproductive organs of the Pteridophyta Cryptogamia is given under the articles Filicis, S. 2, and Musc. That the organs there described may be regarded as containing the two elementary cells, which we have called germ-cells and sperm-cells, is now matter of little speculation. Mr. Horace in a report, made to the British Association, in Oxford, 1861, says, in regard to the question of sexes,—

"We have several kinds of evidence:

1. The inferences to be deduced from the uniformity of the existence of two kinds of organs in connection with the reproductive process. We have seen that these exist in all the families at some period or other of the life of the representative of the species. In the Mosses and the Hepaticas they occur in the fully developed plant. In the Ferns and Equisetaceous they occur upon cellular structures of frondose character developed from all the spores, which frondose bodies or pro-embryos have an existence of some permanence, especially in the Equisetaceous. In the Lycopodioaceae, the Isoetaceae, and Rhiachoaceae, the pistillidia occur upon very transitory cellular structures developed from one kind of spore, the larger, whilst the smaller spores at once develop in their interior cells containing moving spiral filaments such as occur in the antheridia of the other families.

2. That we are deduced from the above observation on the development of those plants in which the two kinds of organs, occurring in distinct places, can be separated. Strong evidence has been brought forward that the dioscorous Mosses, as at least, do not produce sporangia when the pistillidia are kept apart from the antheridia by natural accident. The majority of observers state that the large spores of the Rhiachoaceae do not germinate if the small spores are all removed from contact with them; a few counter-statements have been found. Again, the majority of authors, and all the recent ones, state that only the large spores of the Lycopodiaceae and Isoetaceae produce new plants; whilst some older writers believed that they had seen sporangia in all species do so.

3. The direct observation of a process of fertilisation, of which we have only testimony from two authors, Suminaki and Mercklin, in reference to the Ferns alone; since the assertions of Schleiden in regard to the Rhiachoaceae have been demonstrated by Nageli, Hofmeister, and Meinert to have been based on very imperfect observations.

To the question as to the homologues of the organs in the higher Cryptogamia, Professor Hufnagel gives the following answer:

"In the Mosses and Hepaticas the pistillidia occur upon the plant when the vegetative structure is perfect, and the immediate product of the great cell is a sporangium. If a process of fertilisation take place here, we may regard the antheridia, stamens, as analogous to the anthers and pistils of flowering plants, the sporangia of their fruits; with Hofmeister we may regard the phenomenon as an instance of an 'alternation of generations,' where the sporangi-
This is the embryo. The prolonged part subsequently dies away.

The development of the pollen-cell is more uniform in the different families of plants. The part at first appears in the young flower-bud as a little cellular papilla. In process of time this papilla divides into two portions. These are the rudiments of the future loculi, or valves. In each half, a single axial vertical column of cells soon becomes distinguished by its greater size and granular contents. In each of these cells the nucleus disappears, and is replaced by two others; this being followed by a division of the cell-contents, which form the primordial circle, into a new cell round each nucleus. This process is repeated, and a mass of cells is thus formed which

**Germination**

loses its spherical shape, and becomes elongated, forming the so-called pollen-tube. It is this tube which, passing down the style, becomes applied to the embryo, and is the cause of the development and growth of the embryo. A question has, however, arisen as to whether the pollen-tube acts dynamically upon the embryo, or becomes part and parcel of the new embryo. Granular contents of the pollen-tubes be followed into the ovule, it will be found that usually one, and rarely more penetrates the intercellular passages of the nucles and reaches the embryo-sac, which is being forced forward, is pressed and indented, and by its folding-in, forms the embryo in the first stage of its development. A log is thus formed consisting of a double membrane, the indented embryo-sac, and the membrane of the pollen-tube itself. Schleiden infers the identity of the embryo and the pollen-tube from the three following circumstances:—1. The constantly equal diameter of the pollen-tube when it is just within the ovule. 2. The invariable chemical similarity of their contents shown by the reaction produced by the application of acids, oil of sweet almonds, iodine, ethyllic acid, and alkalies. The general contents of the grain of pollen are starch, and this either proceeds unchanged downwards through the pollen-tube, or else passes along after being changed by a chemical vital process into a transversally divided, uncountable fluid, which becomes gradually more and more opaque; and is coagulable by the application of alcohol; out of this, by an organising process, the cells are produced which fill the ends of the pollen-tube, extending in Orchis Morio far beyond the ovule, and thus forming the parthenogamy of the embryo. 3. The identity of the embryo and the pollen-tube is further supported by the fact, that in such plants as bear several embryos, there is always precisely the same number of pollen-tubes present as we find embryos developed.
Those views of Schleiden, with his conclusion that the pollentube should be regarded rather as the representative of the female than of the male in the animal kingdom, have been adopted by Wyder of Berne and others.

On the other hand, observations were made by Mirbel, Mirbel and Spach, on another class of plants, in which they did not meet with the structure described by Schleiden, and consequently they object to the general application of his conclusions. They examined the development of the ovule of the family Loranthaceae, and found the ovule to consist of two very elongated, cylindrical, structures, resembling the true embryo-sac, but they found the commencement of the embryo, which they call the primary nitch, and which Schleiden described as the result of an involution of the sac, existing in the cavity of the nucleus sac, was also an embryo-sac, as described by Schleiden, existed in the embryo. They also found in other plants the primary nitch existing in the interior of the embryo-sac, and at a period anterior to the act of impregnation. They therefore conclude that the pollentube does not become the embryo, and that no involution of the embryo-sac takes place. Their conclusions are probably as much too general as those of Schleiden.

Mr. Griffiths, in a paper published in the 'Linnaean Transactions,' gives the result of a long series of investigations on the development of the ovum in the genera Santalum, Oryis, Loranthus, and Visetum. From his observations on these plants, which differ from those investigated by Schleiden, and Mirbel and Spach, he has arrived at conclusions that must have some way of being contested by other observers, and he carefully refrains from drawing an inference from the facts which he has observed that would apply to the whole vegetable kingdom. "The first process," he says, "is the formation of a sac, which is entered by the pollen-sac, and the absorption of the boyan (the pollentube) to the embryo-sac would, in Santalum, Oryis, Loranthus, and Visetum, appear to consist of the formation of cellular tissue. This may be applied, I believe, to most if not to all instances. This cellular tissue appears to have two different origins—one, and this is the earliest in development, being perhaps referable to the embryo-sac, while the other appears directly referable to the anterior ends of the pollentubes. Thus far he agrees with Schleiden, that the ovule is formed from the into the embryonal sac, and that the embryo is derived from its intuited extremity. His observations on Santalum and Loranthus confirming this fact, whilst Oryis is an exception confirmative of the rule. But none of my observations, says Mr. Griffiths, have tended to confirm Schleiden's idea of the infection of the embryonic-sac before the pollentube; and it appears to me sufficiently obvious, that if such were the case the cylindrical bag (the primary nitch of Mirbel), consisting of the ovule, the embryo in its first stage of development, would consist of that portion which is derived from the first, or outer, of the ordinary and unaffected membrane of the sac; the second, of its inflected portion; the third, that of the pollentube itself. He also expresses his conviction that in the earliest period of the plant's existence, Messrs. Mirbel and Spach is the sac of the embryo, which no doubt often and perhaps generally exists before fertilization.

Dr. Murr has published a paper in the same volume of the 'Linnaean Transactions.' He made a series of observations upon the ovum of the Tropoeolum majus. He concludes from his observations on the Tropoeolum majus, "that in this plant the primary ovule and the future embryo never exist together as a whole. They always consist of the pollentubes at their first origin, or at any subsequent period of their development, as is sufficiently obvious from the fact that the pollentube is never brought into contact with the embryo-sac. As the primary ovule makes its appearance before impregnation has occurred, it cannot be possible that the organ has ever formed the extremity of the pollentube, as is believed by Schleiden and Wyder. Moreover, as the primary ovule takes its origin wholly with the ovule-sac, and at the earliest period of its formation it is not in contact with any of the ovule-cells, it cannot have formed by the pollentube pressing before it a fold of the embryo-sac in its passage into the cavity of that structure, as Schleiden has maintained."

Our friend Dr. Richard Hull, in his 'Elements of Botanical History,' 1852, Professor Henfrey has published a paper on the Reproduction of the higher Cryptogamia and Phanerogamia, in which he states that he has not been able to observe the penetration of the pollentube into the embryo-sac.

We now pass to the consideration of the function of Reproduction amongst Animals. General Reproduction occurs in many of the lower animals in the same manner as plants. There is a common reproduction of destroyed tissue, which frequently extends to the production of an entire limb. This is seen amongst the Radiata, especially the Echinodermata, also amongst the Articulata. The highest families of animals in which this kind of reproduction occurs regularly are the Reptiles, in which instance the eggs or young animals are not destroyed. Observational instances occur in which the limbs of higher animals are reproduced. The case of a Thrush, in which such renewal had taken place in a leg, was brought before the British Association meeting at Hull. A case of this kind also occurred in a bird at the British Museum, having been removed, it was again reproduced almost entirely.

Reproduction by division into two, or by gemmation, the Filifarious and Gemmiparous methods of Reproduction, occur to a very considerable extent among the lower animals. These modes of reproduction do not occur alone, but both occur in the same families of animals. [Hydra, S. 2; Polyzoa, S. 9.] The individuals which are thus produced by fission or by gemmation are called Zooids. This process occurs in unicellular as well as multicellular plants and animals, and the single cells produced by the division of the Desmidieon, the Diatomaceae, and the Vorticelline, are as much entitled to the term Zooids as the more complicated forms of the Algae.

The true generative act is performed in animals in the same manner as in plants. In order to the production of the new individual it is necessary that there should be a union of germ-cells on the one hand with sperm-cells on the other. We shall not here attempt to describe the various forms of animals, in which this union occurs. The germ-cells are usually produced from tissues and organs that are structurally different, but as in plants these organs may be placed on different individuals, or on the same. When the two sets of cells are produced in the same individual, these cells are said to be Hermaphrodite; but if these cells are found on different individuals they are said to be Monosexual. The term hermaphrodite is also applied to plants; but when their sperm-cells and germ-cells are placed on different flowers, as happens sometimes in the Phanerogamia, they are called Monocious and Dioecious.

The sperm-cells in the animal kingdom assume a more definite form than those of the vegetable kingdom. In the higher Cryptogamia, where they assume the form of cell-like filaments, or cytoplasm, they never occur as sperm-cells in the animal kingdom. These filaments are formed in the interior of cells, from which they escape by bursting. They usually present an elongated filamentous appearance, with a slight club-like extremity. The spermatogenous tissue is therefore a kind of animalcule, and called spermatogenous, and are supposed to have an interior organisation. This is not the case, and they have no more claim to be regarded as animalcules than moveable blood-discs, or ciliated epithelium.

Dr. Murr has performed by these bodies are in many instances due to the presence of cilia, which are found upon their surface. The movements of such filaments would vary according to the disposition of the cilia. In other cases they present an elongated filamentous appearance, with a slight club-like extremity. At one time they were added as a kind of animalcule, and called spermatogenous, and were supposed to have an interior organisation. This is not the case, and they have no more claim to be regarded as animalcules than moveable blood-discs, or ciliated epithelium.

1. In the spermatic fluid, taken from the epididymis and vas deferens, motile spermatic filaments exist in very great abundance.

2. In more or less aqueous solutions of all innocuous indifferent substances and salts, the motion of the filaments ceased, and they form loops.

3. These filaments, thus furnished with loops, are not dead, as has hitherto been generally believed; for on the
19. The sperm-fluid dried in indifferent substances, and in saline solutions, may, in certain cases, have its motion restored by dilution with the same fluid, or with water.

20. The organs which give origin to the spermatic filaments are unpaired; they increase in size, and at last present a corpuscle (seminal corpuscle) in their interior. These corpuscles, as we have seen, are gradually converted into the spermatic filament, which is at first a very fine thread, and lies in contact with the inner surface of the wall of the corpuscle. The spermatic filaments usually present themselves in clusters, which arise from their tendency when set free to arrange themselves in this manner.

The size of the spermatic filaments varies. In human beings they are from 1-500th to 1-5000th of an inch in length. The head is about 1-5000th to 1-50000th of an inch long, and about half as broad.

In the females of most animals it is not difficult to find a large cell, which is called an ovum or egg. If this ovum be examined in the Mammalia, it will be found to present a vesicle, which is called the germinal vesicle, and this ovule presents a spot, called the germinal disk. There seems to be little doubt that this vesicle is really the ovum.

In the Mammalia the ovum is found in an organ called the ovary.

If the structure and formation of the human ovary be examined, we are led to believe that it is a very ancient organ, but especially during that period of life in which the power of conception exists, it will be found to contain, on an average, from fifteen to twenty small vesicles or membranous cases of various sizes; these have been already alluded to as the follicles of the ovary. This envelope or tunica is accurately described at their first formation, the Graafian vesicles are small, and deep-seated in the substance of the ovary; but as they increase in size, they make their way towards the surface, and when mature they form little prominences on the external surface of the ovary, covered only by the peritoneum. Each follicle is formed with an external membranous envelope composed of fine fibro-cellular tissue, and connected with the surrounding strata of the ovary by a network of blood-vessels. This envelope or tunica is lined with a layer of nucleated cells, forming a kind of epithelium or internal tunica, and named membrana granulosa. The cavity of the follicle is filled with a limpid fluid, in which microscopic granules float; and it contains also the ovum or ova. The ovum is a minute spherical body situated, in immature follicles, near their centre; but in those nearer maturity, in contact with the membrana granulosa, at that part of the follicle which forms a prominence on the surface of the ovary. These granules of the membrana granulosa are at that point more numerous than elsewhere, and are heaped around the ovum, forming a kind of granular zone, the discus proligerus.

In order to examine an ovum, one of the Graafian vesicles, it matters not whether it be small or large, to examine it when at maturity, should be pricked, and the contained fluid received upon a piece of glass. The ovum then, when found in the midst of the fluid by means of a simple lens, may be further examined with higher microscopic powers. Owing to its globular form, however, its structure cannot be seen until it is subjected to gentle pressure.

The human ovum is extremely small, measuring, according to Bischoff, from 1-240th to 1-130th of an inch. Its shape is very irregular: it is a discus proligerus of 1-5000th of an inch in thickness, which, under the microscope, appears as a bright ring, bounded externally and internally by a dark outline: it is called the zona pellicula, or vitelline membrane, and corresponds with the chorion of the impregnated ovum. It adheres especially to the heap of cells constituting the discus proligerus.

Within this transparent investment, or zona pellicula, and usually in close contact with it, is the yolk, or vitellus, which is composed of granules and globules of various sizes, but more especially those which are heaped around the ovum, which are the more numerous, resemble in their appearance, as well as their constant motion, pigment granules. The larger granules, or globules, which have a sapphirine-blue hue, are scattered in the periphery of the yolk. The number of the granules is, according to Bischoff, greatest in the ovum of carnivorous animals. In the human ovum their quantity is comparatively small.
The substance that combines the protuberances and granules of the yolk is in many animals quite fluid. The yolk then completely fills the cavity of the zona pellucida, and escapes in a liquid form when that membrane is ruptured: but in ova of the human subject, and some animals, the yolk is much more consistent, and sometimes escapes as a solid globule. The zona pellucida, according to Bischoff, solely owing to this firm consistence of the yolk that it in many cases preserves its form when a watery fluid passes by imitation through the zona pellucida, and that the sperm enters then between the yolk and that membrane.

From the appearances resulting from the action of water on the ovum, and from other circumstances, it has been thought that the mass comprising the yolk is surrounded by another membrane within the zona pellucida, but the evidence upon the point is not satisfactory. That is, in the yolk itself.

"In the substance of the yolk is imbedded the germinal vesicle, or vesicular germinaltv. This vesicle is of greatest relative size in the smallest ova, and is in them surrounded closely by the yolk, nearly in the centre of which it lies. During the development of the ovum the germinal vesicle increases in size much less rapidly than the yolk, and comes to be placed nearer to its surface. In a mature ovum of the rabbit it is about one-sixtieth of a line in diameter (Bischoff)." (Wagner.)

The act of fecundation is effected in the same manner in animals as in plants, that is, by the contact of the sperm-cells with the germ-cells. Much discussion has taken place as to whether the sperm-cells are fertilizing, as they are regarded as embracing the facts most generally accepted:—

As the germinal vesicle becomes fitted for fecundation, it loses its pellicular character, arising from the development of a large number of cells in its interior. It is at this period that the sperrmatic filaments, coming in contact with it, produce that tendency to growth which results in the formation of the new being.

The nature of this contact has been a question. Mr. Newport, however, in a series of very carefully-conducted experiments upon the Amphibia, comes to the conclusion that the spermatic filament penetrates the vitelline membrane, and comes directly in contact with the germinal vesicle. There is no special foramen for the admittance of the spermatic filaments, but they pierce through this membrane, and are first seen in the vesicle in the way of Mr. Newport found that a single spermatozoan did not produce fecundation, but that the penetration of several were required for its purpose.

The sperm-cells of birds and other animals are brought from the ovariess along the Fallopian tube into an organ called the uterus. It grows rapidly after reaching the uterus; it at first consists of two sacs, one including the other, and the inner containing a liquid. When it is about half a line in diameter a new element becomes visible: it is a delicate, opaque, granular disc, seen, with a dark spot in its centre, upon the surface of the internal globule or sac. This spot, which is seen either on or through the inner membrane of the ovum, corresponds with the cisticruncula of the egg, and is the first rudiment of the fetus.

In birds the cisticruncula, or germ-spot, lies upon the surface of the yolk: soon after the commencement of inhibition it extends and separates into two leaves; the latter is called by Pander the serous layer, and subsequently forms the osseous, nervous, muscular, and taumaturgic systems of the body; the inner, which is in contact with the yolk, is called the mucous; which (together with a third developed between them and the serous layer) appears to give rise, by the changes it undergoes, to the intestinal, respiratory, vascular, and glandular systems. The mucous layer of the germinal membrane gradually expands over the yolk, and nearly incloses it in a sac, which towards the body of the ovum thins into the integument, which extends the whole length of the embryo, and becomes the future alimentary tube. The sac containing the yolk, and communicating with the intestines, is called the intestinal vesicle, or yolk-bag, and towards the close of incubation is drawn into the belly of the chick, and its contents are used as nourishment. The lower end of the alimentary canal (the cloaca of birds) shoots out into a sac which is termed the allantois, or allantoic membrane. After a time arteries and veins are seen ramifying upon this sac. Whether it is a cylindrical tube, till at length it forms a double bag, laid immediately under the membrane of the shell. On this sac the blood-vessels are so distributed that their contents are influenced by the atmosphere through the osseous and vertebral membrane, and thus a true respiratory organ is established.

The original structure of the ovum, and the early development of the embryo, in Mammalia, appear to be much the same as in the egg of a bird; though there are some characteristics which are peculiar to that class. When an ovum of the human species is examined, the embryo is seen suspended in a loose bag filled with fluid, called the amnion, which is a sort of sac: this sac is the outermost product of the serous layer of the mist. In the formation of its formation a large part is reflected from the sides and extremities of the embryo (the reflection, according to Valpeau, not commencing before the twelfth day), so as to inclose a space behind it. As the walls of the trunk close in front, the circle at which the amnion is inclosed becomes attached to the inside of the sac, thus forming the chorion. The mucous layer of the germinal membrane, becoming attached to the outer layer of the amnion, is called the chorion, and is surrounded by a watery sac, as in birds, containing a yolk, or substance subservient to the nourishment of the fetus in its early stage. Whether this view of its formation and use he correct or not only rests on analogy; but in the early part of gestation, the outer amnion is sometimes seen as a tube, the cavity of which is lined with its covering, and the walls of which are thickened in the form of the intestine. In Mammalia it is in this circumstance that in the former it is not drawn into the body of the foetus, but remains without between the membranes, and gradually wasting becomes obliterated by the third month. The duct of the umbilical vesicle is accompanied along the cord by an artery and vein, which are called the omphalo-mesenteric vessels; the artery communicating with the superior mesenteric, and the vein with the vena porta. The allantois exists in all mammals as a tube in the hind part of the body, but is sometimes furnished with a placenta, which is not obvious. In some animals, as in man, it becomes obliterated at a very early period, as soon as the sixth week, but in others, as the Cervidae, &c., it is still traceable at the birth of the animal. The channel of communication between the allantois and the bladder, or cloaca (in birds), at first is short, so that the sac lies directly against the body of the embryo, but it afterwards becomes elongated, like the corresponding duct of the umbilical vesicle.

In man, after impregnation has taken place, a saccular membrane is formed on the inner surface of the uterus by an exudation of lymph. This membrane, called decidua, lines the whole of the uterus before the descent of the ovum; but when this passes down through the Fallopian tube it gradually passes the decidua, and reaching it in the cavity of the ovum, is supposed to be formed by the decidua reflexa; this grows with the ovum till it fills the cavity of the uterus, and comes in contact with the other portion called the decidua vera, lining the walls of the uterus.
membrana decidua, which is also thick and vascular. This thickening and vascularity of both these membranes gradu-
ally increases, and finally, after the umbilical portion of the cord is formed, the placenta is completely surrounded by the chorion, and is usually towards the fundus of the uterus; this thickened part is called the placenta. In ruminating animals the thickening and vascularity of the chorion is confined to a number of rather spongy elevations, varying in number from thirty to one hundred, and in height from 0.03 to 0.08 inches.

These vascular processes dip in between corresponding pro-
cesses attached to the uterus of the mother, which are called maternal cotyledons, the surface of which is supplied with numerous vessels, and in no way is it separated from the chorion by those of the fetus through the fine intervening membranes by which they are separated. In man the relation between the maternal and fetal systems is not so clearly understood as in the preceding instance. In the human subject the placenta is a spongy vascular mass like a cake, from six to eight inches in diameter, about an inch thick in the middle, and two or three lines at the circumference. It adheres by one surface to the uterus, and by the other is connected with the chorion, and the surface being lobulated, and is connected with the uterus by blood-vessels. The fetal surface is covered by the chorion and amnion, and presents the ramifications of the umbilical vessels, which consist of two arteries and a vein. The ramifications of the umbilical vessels are about two inches long, and no communication has ever been shown to exist between them and the utero-placental vessels; for if we inject from the umbilical arteries we find that the placenta is rendered turgid, and that vessels are found filled in every part of it, but between their ramifications there will remain an unin-
jected substance, and the uterine surface will not be injected, for the fetal vesseis do not pass all the way to that surface. In like manner, if we inject from the uterine vessels, the placenta will be filled, and relatively the same branch will pass into the fetal vessels. From this circumstance it is concluded that the placenta consists uniformly of two portions: the one is furnished by the deciduous coat of the uterus, the other by the vessels of the chorion, and these two portions may, during the first three months, be separated from each other by maceration. The structure of the fetal portion, so far as can be made out, appears to be similar to that of the pul-
monary vessels, the artery terminating in the vein. But the matter is by no means so simple as has been generally con-
cluded, as Mr. Hunter thought, to terminate in irregular cells, and the veins appear to com-
ence with open mouths from these cells, for by throwing wax in the uterine vessels we fill the cells, and frequently in the shape of miniature vesicles. It has always been considered doubtful whether the placen-
cal cells of Hunter were real or artificial, being, in the latter case, produced by extravasation of the injection; and recent researches have confirmed this doubt, but without throwing any satisfactory light on this very obscure subject. With regard to the use of the placentae we may infer that it is very similar in man to what it is in ruminating and other animals: it most probably serves to produce a change in the blood of the fetus analogous to that which the blood of the adult undergoes in the lungs; and, from considering that the fetus itself cannot create materials for its own growth and support, we may further infer that the placenta is the source of nutrition also.

The navel-string, or umbilical cord, which connects the child to the mother, is composed of the umbilical vein and two umbilical arteries twisted together, and surrounded by a gelatinous substance and the reflections of the chorion and amnion; it also contains the urachus, and the remains of the duct of the allantois. The umbilical artery and vein is at the same time the duct of the umbilicus; and in the same way the chorion, which is also reflected on the navel-string, is continued into the dermis, or true skin of the fetus.

The following is Valentin's account of the development of the principal organs of the human embryo.

"The primitive streak or groove is the first indication of the future embryo. It consists of a very small longitudinal groove in the middle of the upper surface of the serous membranes, composed of processes which are raised to form the laminae doraels. They grow over towards each other, meet in a longitudinal suture, and thus inclose a cavity, the primitive tube. Anteriorly this tube dilates into several vesicles, which lie behind each other, and in which is deposited a jelly-like substance. The spinal cord is laid down in its remaining cylindrical portion. The several parts of the brain of the human embryo gradually pass through numerous transitional forms, which correspond with their permanent parts. In this state the brain is analogous to a fruit in its embryo state, having a hard coat or shell, composed of a fibrous substance, and a jelly-like substance in its center. The brain is surrounded by a spongy substance, the gelatinous amnios; gelatinous amnios; the face, and the other portions of the body may be compared with vegetable matter in its embryonic state. In this condition the brain surface is covered with a jelly-like substance, which becomes the cerebral engine. The brain surface is composed of two layers of cells, which fill the cavities of the jelly-like substance, and are separated from each other by a jelly-like substance, which is the jelly-like substance of the cerebral engine. The brain surface is composed of two layers of cells, which fill the cavities of the jelly-like substance, and are separated from each other by a jelly-like substance, which is the jelly-like substance of the cerebral engine. The brain surface is composed of two layers of cells, which fill the cavities of the jelly-like substance, and are separated from each other by a jelly-like substance, which is the jelly-like substance of the cerebral engine. The brain surface is composed of two layers of cells, which fill the cavities of the jelly-like substance, and are separated from each other by a jelly-like substance, which is the jelly-like substance of the cerebral engine. The brain surface is composed of two layers of cells, which fill the cavities of the jelly-like substance, and are separated from each other by a jelly-like substance, which is the jelly-like substance of the cerebral engine. The brain surface is composed of two layers of cells, which fill the cavities of the jelly-like substance, and are separated from each other by a jelly-like substance, which is the jelly-like substance of the cerebral engine.
The pulmonary artery and vena cava of the new-born infant are connected with each other by means of the ductus arteriosus and venosus, respectively. The ductus arteriosus is situated at the first visceral arch. The external ear is produced last of all.

The organs of smell are also first indicated by vesicles, which are connected with the brain. The nose is developed after the external ear; it is a conical appendage, which is subsequently laid down, ends by separating the cavities of the nose and mouth. The tongue grows out of the first maxillary arch. The external integument is only separated into a sheet of skin of the body, which covers most of the body, and is capable of protecting it like an ointment from the injurious action of the liquor amni.
both systems of vessels. The purified blood is brought from the placenta by the umbilical vein, and is mixed before arriving at the heart with that which has been circulating through the fetus: the mixed blood is then transmitted by the sorts to various parts of the body; some of it only going again to the placenta by the umbilical arteries to be again purified.

The position of the child in the uterus is that which takes up the least room: it lies with the head downwards, the chin being bent on the breast; the knees are doubled up, and the arms are close against the body, the one across the body and the other between the head and legs. This is the most general position, and the child thus forms an oval figure, of which the head forms one end and the breech the other. The long axis of this ellipse measures in the ninth month fully ten inches, and the breadth five or six inches. The quantity of fluid which surrounds the child at the full time is, on an average, about two pints.

The ordinary period of utero-gestation in man is forty weeks, though labour often takes place before this period, or is delayed a little beyond it. The embryo having now arrived at a sufficient degree of maturity to exist separately, the fibres of the uterus contract, accompanied by contraction of the abdominal muscles and diaphragm. In consequence of these circumstances the fetal body, by a force from the womb; they then burst and evacuate the liquor amnii in which the pressure acts upon the child itself, which is gradually forced into the world, and commences a new existence. In man, and other Mammalia, the young being for a time in the abdomen, in which the length of the body is lost in the circumference of its nourishment, and generally requires a supply of warmth and a degree of protection till it is able to provide for itself.

RESPIRATION is that function in the animal kingdom by means of which the various tissues of the body are exposed to the chemical influence of the gases of the atmosphere, and the products thus formed expelled from the body. The advance of chemical knowledge has demonstrated that this function is one essentially of oxidation, and hence it has become the object of removal of the oxygen, and the retention of the carbonic acid and other gases of the lungs, gills, or sacs, are organs where the blood receives the oxygen gas, and gets rid of its carbonic acid; whilst the capillaries of the systemic circulation are the organs by which the oxygen is transmitted from the lungs to the body, and the carbonic acid. The process of respiration then is the same in the highest as in the lowest animals, with this exception, that in the lowest animals there are no organs of circulation, and no organs of ventilation, as the lungs and gills may be called, for carrying the oxygen and carbonic acid to and from the tissues.

The absorption of oxygen by the animal cell seems to affect three great objects:—1. The preparation of the materials taken up as food for the purposes of nutrition. 2. The production of heat, for the warm-blooded animals which have been supplied with oxygen, are said to be kept warm by this deprivation, but all; so that we find the amount of oxidation performed by this process becomes the exponent of the amount of vital activity displayed by any particular animal, or class of animals. When the functional activity of any animal is greater than that of another, the former will be found to contain more oxygen, and carbonic acid, than when it is small. Thus, in animals which hydrobates, the amount of oxygen consumed, and carbonic acid given out, is much less during their period of rest than when in the period of activity. Sluggish and slow-moving animals consume less oxygen than those which are active. Thus the Mollusca consume less oxygen than the various tribes of active insects. It is also found that animals whose movements are slow will support the absence of oxygen gas for a very much longer time than those whose movements are quick.

Under the head of the various articles devoted to the classes and families of animals some account is given of the general character and structure of what are called the Respiratory Organs, which convey the oxygen from the air to the whole surface of the animal exposed to the fluid in which they live, and which contains the oxygen necessary to produce the respiratory changes. When a number of cells are aggregated into a mass, as in the lungs or gills, the simple vessels are formed, special provision is made by means of cilia, or molecular movements, for carrying the fluid into these cavities, or tubes, as seen in many of the polygastric anaerobes and the sponges. Passing higher in the scale of animate beings we find the aquatic forms introducing water into the interior of the animal becoming more complicated, till in the Holothurian we find a special system of vessels for supplying this fluid, which have been called an 'aeriferous', or 'water vascular system,' and which becomes more fully developed in the Echinoderms, the lowest tribe of the Articulata.
These arrangements amongst the lower animals are preparatory to the two predominant forms of respiratory apparatus which are found in the higher animals. The provision for supplying the system with oxygen is in them made by means of a fluid carried, and which is a circulation of the apparatus to all parts of the body. This circulating apparatus brings the blood in contact with the air by one of two arrangements. Either the serous organ is a projection from the surface of the body, when it is called a Gill; or it is a depression in the surface, when it is called a Sac or Lung. The first of these arrangements is found in all animals which breathe through the agency of water, whilst the second is found in those which breathe air. In the Aquatic Mollusca, the Graparia, the Annelida, and the Crustacea, larva of insects, the fishes, the tadpole condition of the Amphibia, and the perennibranchiate forms of that family, we meet with a vast variety of forms of gills adapting these animals to lead an aquatic existence. On the other hand, we find in the Terrestrial Mollusca and the Insects the simplest forms of air-breathing apparatus; whilst in the Reptiles, the Birds, and Mammalia, we have varied forms of lungs.

Man breathes by means of lungs. The structure and arrangement of those organs, and the nature of the movements performed by the muscles which contribute to the performance of their peculiar function, are described under the article Lungs. The lungs of man are so constructed that they cannot be filled with water by the most violent efforts of the circulatory expansion, a certain quantity of air is taken into the lungs, and this act is called inspiration. This inspiration is followed by a corresponding collapse, during which the lungs occupy a smaller space, and a certain quantity of air is expelled—this is called expiration. The quantity of air taken in and that expelled by the human lungs at each respiratory effort varies. It is however easily measured by blowing into a vessel filled with water or other fluid, when the amount of fluid displaced will be the measure of the quantity of air thrown out from the lungs. Instruments of this kind, called spirometers, under the name of Spirometers, are now frequently employed as a means of diagnosis in diseases of the chest. The difficulty however of securing freedom from disturbing causes renders the spirometer less useful than the apparatus for expiration could be wished. The quantity of air thrown out from the lungs has been variously estimated, but probably from 20 to 25 cubic inches is near the truth. Scharling conducted a series of experiments upon the quantity of carbonic acid gas thrown out of the lungs by persons of different ages and various ages. The following table gives an idea of the average relations of the excretion of carbonic acid gas during one hour:

The air that is habitually and almost uniformly changed in breathing is by Mr. Hutchinson called Breathing Air. The oxygen is then certain that by means of the lungs, which may be expelled by a forcible and deeper expiration: this he terms Reserve Air. But even after the most violent expiratory efforts the lungs are not completely emptied; a certain quantity always remains in them, over which the spirometer gives no indication and which may be called Residual Air. Its amount depends in great measure on the absolute size of the chest, and has been variously estimated at from 40 to 260 cubic inches.

The greatest respiratory capacity of the chest is indicated by the quantity of air which a person can expel from his lungs by a forcible expiration after the deepest inspiration that he can make. Mr. Hutchinson names this the Vital Capacity; it expresses the power which a person has of breathing in the emergencies of active exercise, violence, and disease; and of a healthy man it varies according to stature, weight, and age.

"It is found by Mr. Hutchinson, from whom nearly all our information on this subject is derived, that at a temperature of 60° Fahr., 225 cubic inches is the average vital capacity of a man of 5 ft 6 inches in height. For every inch above height above this standard the capacity is increased on an average by 8 cubic inches; and for every inch below it is diminished to the same amount. This relation of capacity to height is quite just, and may be fairly attributed to the cavity of the chest; for the cubic contents of the chest do not always or even generally increase with the stature of the body, and a person of small absolute capacity of chest may have a large capacity of respiration, and vice versa. The capacity of respiration is determined only by the mobility of the walls of the chest; but why this mobility should increase in a definite ratio with the height of the body is yet unexplained, and must be difficult of solution, seeing that the height of the body is chiefly determined by the height of the leg, and not by that of the trunk or the depth of the chest. But the vast number of observations made by Mr. Hutchinson leave no doubt of the fact as stated above.

"The influence of weight on the capacity of respiration is less manifest and considerable than that of height; and it is difficult to arrive at any definite conclusions on this point, because the natural average weight of a healthy man in relation to stature has not yet been determined. As a general statement, however, it may be said that the capacity of respiration increases with age and weight. The experiments of Mr. Hutchinson on infant and on men of 5 feet 5 inches in stature showed that 10 cubic inches would be able to expire 217 cubic inches, one of the same height, weighing 12 lbs might expire only 303 cubic inches. By age the capacity appears to be increased from about the 15th to the 35th year, at the rate of five cubic inches a year, so that at 35 the capacity of a man of 5 feet 5 inches is 32 cubic inches greater than at 10. Again, the capacity decreases as the stature increases, so that the average of men of 6 feet can expire only about 1½ inches of mercury. The force manifested in the strongest expiratory act is, on the average, one-third greater than that exercised in inspiration; but this difference is in great measure due to the power exerted by the elastic reaction of the walls of the lungs, and it is also much influenced by the disproportions of strength which the expiratory muscles sustain through being called upon to act for other purposes than inspiration. The force of the inspiratory act is therefore better adapted than that of the expiratory for testing the muscular strength of the body.

"Much of the force exerted in inspiration is employed in overcoming the resistance offered by the elasticity of the walls of the chest and of the lungs. Mr. Hutchinson estimated the amount of this elastic resistance by observing the elevation of a column of mercury raised by the return air forced, after death, into the lungs, in quantity equal to the amount of air contained in the lungs, and which of necessity was the same as the air in the trachea. It was found that in a man capable of breathing 300 cubic inches of air, the muscular power expended upon the elasticity of the walls of the chest, in making the deepest inspiration, would be equal but for the use of force other than that of inspiration. At least, at a calm or tranquil respiration, supposing the amount of breathing air to be 20 cubic inches, the resistance of the walls of the chest would be equal to lifting more than 300 lbs. The elastic force exerted in ordinary expiration must therefore be much

* The kilogram is 2.205 lbs. very nearly. The gramme is 15.434 grains.

it has been found that the carbon and hydrogen of nitrogenous foods become oxidised, and are given out during respiration, but they do not supply sufficient for the wants of the system, and when animals are fed on nitrogenised foods, the fat is oxidised and converted into carbonic acid and water.

It appears to be now an established fact, that the inhibition of spirituous drinks of all kinds is attended by a diminished excretion of carbonic acid. This was indicated by Prost and has since been confirmed by Vierordt and others. This shows the importance of such drinks in cases where the oxidating processes are proceeding too rapidly, and of their injurious tendency where these processes need to be stimulated. Dr. Prost observed that strong tea exercises the same influence on the system.

Sleep produces a very considerable diminution of the excretion of carbonic acid. Schaarling found that the ratio of carbonic acid exhaled during sleep in one hour in the night, to that eliminated in one hour in the day after dinner, was 31:39 to 40:74. A much greater difference is found between animals during their waking and hibernating states.

Bodily exercise increases the exhalation of carbonic acid, whilst rest diminishes it. Seguin, Prost, Vierordt, and Hoffman, have all proved this by experiment.

With regard to the quantity of oxygen consumed during respiration, it was at one time supposed to be exactly equal to the quantity of carbonic acid exhaled in the expired air. This however is not the case, for accurate experiments show that, after all allowance made for oxygen present in the tissues, there is constantly a small quantity more taken into the lungs than is thrown out. The destination of this oxygen is undoubtedly the oxidation of the carbonic acid gas excreted from the lungs, in the formation of the substances found in the bile and urine, and in the formation of phosphoric and sulphuric acids. The quantity of oxygen consumed is nevertheless measured by the carbonic acid thrown off from the lungs, so that, where there is an increase of excretion of carbonic acid, there is an increase of absorption of oxygen.

It is an interesting fact that small animals consume a relatively much greater proportion of oxygen than larger ones.

It also a fact of practical importance that the quantity of carbonic acid gas exhaled is not increased by increasing the quantity of oxygen in the atmosphere. As a proof of the necessity of the changes involved in the absorption of oxygen gas, it has been found that the eggs of birds, and undoubtedly this applies to the eggs of all animals, absorb oxygen and give out carbonic acid. The following table gives the result of some experiments of Valenciennes on this subject—

From this table it may be gathered that vegetable diet consumes more oxygen in the production of carbonic acid and water than animal diet. This is also found to hold good in the case of carnivorous and herbivorous animals—the latter taking up a larger quantity of oxygen than the former.

The nitrogen of the atmosphere appears to act as a diluent, and to temper the activity of the oxygen gas. Although when animals are placed in atmospheres of pure oxygen, or hydrogen, a certain quantity of nitrogen is thrown out from their lungs, it still requires proof that this has been taken up from the atmosphere. It is not improbable that a certain quantity of nitrogen may be thrown off by the decomposition of the nitrogenous tissues in the blood, or excretions.

With regard to the watery vapour which passes off from the lungs, we have already seen that it is sufficient to saturate the expired air. Its absolute amount is therefore influenced by the following circumstances:—1 By the volume of air expired; 2, By the quantity of watery vapour contained in the air previous to its inspiration; 3, By the temperature of the inspired air; 4. By the amount of inspiration, which each volume of inspired air is allowed to remain in the lungs.

We have thus considered the principal physical and chemical phenomena presented during the respiration of animals.

It should however be recollected that these phenomena are...
The expenditure for the year was £51,319,119, under the following heads:

</table>

The expenditure now £70,354,246. The salaries of the Revenue Department form a separate charge, and are no longer deducted as charges of collection before the remission to the Exchequer, and are consequently subject to parliamentary supervision. The National Debt, funded and unfunded, at the end of 1857, was £290,382,099, of which 21,555,410£ was created in 1855. In addition to the sums shown as excess of revenue over expenditure in the preceding years, the greater part of which had been applied to the reduction of the Debt, an Act was passed in 1853 by which the South Sea Stock, a certain Bank Annuities, and Three per Cent. Annuities, were incorporated with the National Debt upon terms which added something to the nominal amount of capital, but produced a large reduction in that of the interest paid. In 1842 the Property Tax, as proposed by Sir Robert Peel, was imposed to remedy the annual desolation in the revenue. It was supposed to touch the pound in all seasons of a good year and upwards. Its effects were visible in 1843, and enabled him to make extensive reductions in the customs and excise duties, to the great benefit of the commerce of the country, as well as the comfort of the inhabitants. The system necessarily interfered with the processes of manufacture—are unavoidably injurious—and are a check upon improvement. In 1797, not fewer than 20 articles were subject to duties of excise. The list included salt, wine, beer, cider, and perry, hides and skins, printed goods, candles, bricks and tiles, starch, soap, starch, linseed, sweets and mead, wickets and glass. There were separate
Boards of Excise for England, Scotland, and Ireland, the functions of which were discharged by 21 commissioners. In 1858 there is only one Board for the whole of the United Kingdom, the number of commissioners has been reduced to seven, and the number of articles in which officers dealt with reports and their regulations, and the amount of work or manufacture has been reduced to four; namely, hops, malt, paper, and spirits. The amount of vexations meddling which has thus been got rid of can only be estimated by those who have had experience of it, and it is to be regretted that in the last years, when the most conscientious respect for the law rendered it difficult at all times to avoid infringements of the regulations of the Board, and when a manufacturer was often at the mercy of the exciseman, and might easily be ruined by a small error, these Business of the regulations of the Excise Board have been simplified in a manner which has greatly lightened the duties of the officers and of the people they have to deal with.

In December 1875, a number of the old excise regulations were renewed for a limited number of years. Sir William Benjamin Disraeli was then Chancellor of the Exchequer, and had already shown his regard for the Excise by several important reforms. He was enabled triumphantly to refer to this popular test. He could show that the effect of remissions of duty, in the way of recovery, was twofold: upon the consumer of the particular article, by enabling him to increase his consumption, and next upon the general consumer, by extending and widening the consumption of the excisable products of the part of the great body of the people. Mr. Gladstone, therefore, proceeded, in reliance upon former facts, to carry on the work of tariff reform on the following principles, as far as his financial engagements permitted it:

1. To abolish altogether the duties which are unproductive, except in cases where there may be some special reason to retain them on account of their relation to other articles.

2. To abolish, as far as revenue considerations will permit, duties which are productive of revenue, but which are a burden to the last stage of finished articles, and are commonly connected with hand-labour, in regard to which it was considered more prudent to proceed in the mode, not of abolition, but of reduction.

3. Whenever it can be done, to substitute rated duties for duties ad valorem.

4. To get rid, except in a few instances where it is important on account of revenue, of the 6 per cent. addition to the duties and the 5 per cent. addition to the duties, in the transaction of business. The articles which the 6 per cent. additional duty is still retained are seven in number, and the duty in question produced 327,167, in 1848; Tobacco, wine, tumbler of British possessions, pepper, gloves, porcelain, and tobacco, a per cent. additional on tins only realized 135,234, and on gloves 1,646.

5. To merge the differential duties in favour of British possessions by lowering the foreign article to the level of the colonial, and where this is not expedient, not to raise the duty on the former of the two.

6. To lower the duties that press on foreign articles of food which enter largely into what may be called the luxuries and comforts of the mass of the people.

The result of this was, that the duty of articles was dealt with on these principles—first the duty was repealed, and on 160 important reductions were made. The immediate loss to the revenue consequent on these alterations was estimated at 1,383,000l. The changes are analogous to those effected in 1843 and 1845-6; and the same result was produced—the gradual recovery of revenue by increased consumption.

The soap duty was entirely abolished, on the ground that it was injurious to health and comfort, that the interference with one branch of the domestic and national improvement, and disabled the manufacturer from competing in markets abroad with the foreign soap-maker, who was free to carry on his business according to the most approved methods, and not under peremptory restrictions; and because the necessary amount of tax is supplied to the extent of one-fourth by textile manufacturers entailed fraud and occasioned great loss to the revenue. It is evident that "considerations of revenue" alone prevented the duty on paper being similarly dealt with.

There were three different rates of duty in the United Kingdom on home-made spirits, and this antiquated mode of dealing with the article led to smuggling. An approximation was therefore made in 1853 towards their equalisation by adding 1s. per gallon to the duty on Scotch spirits, 6d. on Irish spirits, reserving to an early period the further advancement of the principle of equalisation. This was accomplished, as far as regards Scotland, in 1853, by advancing the duty on that kingdom to the same as that in England. By this means the working of the Excise was simplified; the number of excise officers. At the same time the duty in Ireland was raised so as to bring it to so near an approximation, that smuggling almost ceased to be remunerative; and in April, 1868, Mr. Disraeli, then Chancellor of the Exchequer, in his budget proposed an entire equalisation.

Another great object of the Budget of 1853 was to establish a general uniformity of taxation in the three kingdoms under another important head, by rendering Ireland liable to the duties and excises charged in the United Kingdom. The Chancellor of the Exchequer was willing to make a great sacrifice. He remitted a sum of 4,560,000l. due from Ireland to England, constituting an annual charge of 245,000l., three-fourths of which burden would have continued for forty years. He swept away this debt, and commuted the charge in consideration of an addition of 5d. per gallon on Irish spirits, and the income-tax for seven years. Ireland had been exempted
from this tax in 1848, in consideration of a duty of 1s. additional on spirits, and an augmentation of stamp-duities; but the first, was abandoned almost as soon as enacted, and the second disappeared in 1850, when a reduction of stamp-duities took place both in this country and Ireland. Exemption or partial exemption was usually granted to goods imported from Britain; but in the case of Irish goods there was no principle to impose the tax on Ireland, which would otherwise derive advantages at the cost of the people of England and Scotland. The complex system of the assessed taxes, levied under several heads, and claimed, was dealt with, from a view of securing simplicity and uniformity. With this object the progressive plan of assessment has been abolished, also compositions, and, as far as possible, exemptions.

Some important alterations have been made under the head of Stamps. Penny receipt-stamps have been substituted for stamps of varying value, in order to obtain the advantages of uniformity, and to remove the temptation to evasion; and the facilities of trade have been promoted by allowing a penny receipt-stamp to be used in connection with bankers' cheques, so as to add to their security. [Sawv Dunve, S. 2.]

The most important portion of the Budget of 1853 was undoubtedly the new tax on successions, which subjects every estate to duty, whatever is left out of the income-tax, it was alleged, pressed unequally on intelligence and skill, as compared with property, and the succession-tax was designed to adjust the balance. Real property, whether settled or unsettled, had hitherto been exempt from legislation of this kind; claimants were permitted an estate in land of 50,000/. a year to pass to the heir without his contributing one farthing to the state, while a poor man who received a legacy of 100/. paid a tax of 10d. The anomaly has now ceased, and a person who succeeds to a landed estate of 10,000/., is taxed on the annual value of his property, which, on the principle of calculation adopted, gives a rent of 300/. a year.

The income-tax was retained, but was associated with regulations of industrial taxation to an amount exceeding 5,000,000/., and its extinction was finally provided for in 1860, on the ground that it was not well adapted to form a permanent portion of ordinary public income. It is like the reserve of an army, which should only be brought forward to avert great dangers or accomplish important objects. It may reconcile those who dislike the inquisitorial nature of this impost to consider what it has effected under the opposite conditions of war and peace.

Next, which lasted, with two brief intervals, from 1793 to 1816, there were three periods, in the first of which there was no income-tax; in the second it was only incompletely adopted; and in the third it was fully brought into operation. 1773-1786, there was no income-tax. The charge of government, and the charge of debt incurred before 1793, together with the cost of war, amounted on the average of these six years to 36,030,000/. a year. The revenue, with all the additional taxes laid on, amounted to 20,526,000/., leaving an annual deficiency of 15,500,000/.

In 1793, the income-tax was imposed by Mr. Pitt, and from 1793 to 1809, the cost of the war and public charges rose to 47,413,000/.; but the revenue, aided by the income-tax, amounted to 33,726,000/., and under an increase of expenditure, amounting to 11,400,000/., a year, the excess of expenditure over revenue was less by 2,000,000/., a year during these four years than from 1793 to 1798.

In 1815, 1816, 1817, 1818, 1819, and 1820, the income-tax was in full force. The expenses of the war and of government, and the charge of debt (9,500,000/) incurred before 1793, amounted to 65,794,000/., but the revenue rose to 63,780,000/., the annual deficiency, instead of being 7,404,000/., as in 1793, amounted to 2,004,000/.

In 1793, there was actually raised, during the heaviest period of war expenditure, 7,000,000/., a year more than the cost of the war. If the income-tax had been adopted at an earlier period, the national debt need not at this moment have existed. Rightly, therefore, is it regarded as an auxiliary, to be reserved for great occasions. In reimposing the income-tax for seven years, the intentions of the government were to mark it as a temporary measure, to equalise, as far as possible, its pressure on skill and intelligence as compared with property, to mitigate its operation by every rational means compatible with its integrity, and to test of the success of taxation; and on these terms it was accepted for the sake of the benefit which it brought in its train.

The Government, after giving the most mature consideration to the subject, declined to renew the imposition of the tax, because, while it appears to contribute to the success of their general financial plan. The Chancellor of the Exchequer showed that the incidence of the tax on real property was already heavier than was generally supposed, and he considered that the period of 7 years had been paid for by the pound, and that evasion or unfair assessment was impossible; while on trades and professions the principle of self-assessment entailed extensive frauds, of which he gave a striking instance. It was necessary to compensate twenty-eight persons for their profits for a single year, and they claimed 148,590/., a jury awarded 26,973/., but their return of profits for assessment to the income-tax was only 9,000/. The case of the professions, which has often been brought to tax, was raised to 10d. in the pound in incomes of 1,000/. and upwards, to 11d. on farms ranted to that amount; it was reduced to the original 7d. in 1857; and to 5d. in 1858.

"Considerations of revenue" alone prevent the further application of this principle to the financial policy of the fiscal system. The duties on paper and wine, and particularly those on fire-insurance, are amongst the first which have claims to be abolished or reduced, and which promise when relieved from taxation to be productive of the greatest advantage to the general community. It is the wish of the Government to maintain machinery in being against one of the very best principles of society—that of distributing losses which would ruin an individual, over the whole community, in a manner to render it scarcely appreciable by any. An exemption from the tax only shows its futility. Farming-stock and implements do not pay insurance duty, but a workman's tools do. The tax, however, yields upwards of a million to the Exchequer, and the Chancellor cannot afford to give it up. For, the plans have been accomplished, more than could possibly have been anticipated a few years ago; and we will conclude by quoting the closing sentences of Mr. Gladstone's able speech on introducing the Budget in April, 1853, as a fair statement of the principles which now regulate our fiscal system: "While it has expensive reductions of taxation, and when the changes we propose in taxation, to intelligence and skill, as compared with property; while we have sought to do justice to the great labouring community of England, by further extending their relief from indirect taxation, we have not been unmindful of the interests of the community, and we have felt we should best maintain our own honour—that we should best meet the views of Parliament, and best promote the interests of the country—by declining to draw any invidious distinction between individuals, by treating wealth itself as a sacred aim, to diffuse and distribute—burden if we must—benefit if we may—with an equal and impartial hand; and we have the consolation of believing that by
proposals such as these we contribute as far as we lies, not only to develop the material resources of the country, but to knit the hearts of the various classes of this great nation yet more closely than heretofore to that throne and to those institutions under which it is their happiness to live."

As intimately connected with the ameliorations of our financial system, we append a list of the taxes repealed or reduced, and of taxes imposed or increased during the following years —

###REVIVOR. [SORE FACES, &c. 2.]

###RHAYADER. [RADONISHIREE.]

###RHEINITE. [MINERALOGY, &c. 1.]

###RHIZANTHE, Rhizanthe, Echinops, a small class of Plants, comprising the orders Balanophoraceae, Cerinaeae, and Rafflesiaceae. They are parasitical plants, destitute of true leaves, in place of which they are furnished with cellular scales. Their stem is either an amorphous, fangous mass, or a ramified mycelium, and is very imperfectly supplied with spiral vessels, which are sometimes wholly deficient. They are of a brown, yellow, or purple color, never green. They produce flowers which have genuine stamens and carpels, and are surrounded by a whorl of petaloid bodies. They possess ovules, but their seed is not known.

These plants have been regarded by Lindley, Endlicher, and other botanists, as sufficiently distinct to warrant their being placed in a class by themselves. Their flowers, stamens, and ovules, indicate their relation to the phanerogamic plants, whilst their mycelial stem, parasitic habit, and cellular structure ally them with the Fungi and other low forms of vegetation. Mr. Brown however is of opinion that the Rhizanthe asbs are but less developed forms of Eongan Plants. He regards them as having affinities with Aristolochiaceae, and other orders of Exogens. More recently Mr. Griffiths has adopted the views of Brown, and advanced...
many arguments in favour of their being degraded
forms of higher plants, and not a permanently low form
of vegetation. He thinks the relations of Rhizanthes
various. Thus he places Mystropetalum near Protocereus
and Sanctaloea; Sarcoptilis and Balanophora he places near
Utrecchio. Finally, he places Thamnium between Taccaceae
and Balanophoraceae.

The following are the orders of Rhizanthes as recognised
by Lindley—

<table>
<thead>
<tr>
<th>Order</th>
<th>Description</th>
</tr>

<tbody>
<tr>
<td>Ovules</td>
<td>Solitary, pendulous; fruit one-seeded</td>
</tr>
<tr>
<td>Ovules</td>
<td>Ovulate, parietal; fruit many-seeded; calyx 3-4-6-parted; authors opening by alata</td>
</tr>
<tr>
<td>Ovules</td>
<td>Ovulate, parietal; fruit many-seeded; calyx 5-parted; authors opening by Rafflesiaceae ports</td>
</tr>
<tr>
<td>RHIZOBOLACEAE</td>
<td>Ricobola, a natural order of Plants, consisting of trees of very large size</td>
</tr>
<tr>
<td></td>
<td>The leaves are opposite, digitate, coriaceous, with a pointed stalk and no stipules; flowers large, regular, arranged in racemes, with their stalks pointed at the base and below the apex; the sepals are 5 or 6, more or less combined, imbricated in asstivation; petals 5 to 6, equal-sided, but unequal thickish, arising along with the stamens from a hypogynous disc; fruit of several combined indiscernible one-seeded nuts; seed reniform, exalbuminious, with a cord dilated into a spongy exesscence; radicle and scutellum of these species are round. They are large timber-trees, some of which yield edible fruit. It is from this order of trees that are produced the Souari (or Suwarow) Nuts of the shops, the kernel of which is one of the most delicious fruits of the nut kind that is known to man; this nut is especially found inferior to that of the olive. The timber of the tree is used for shipbuilding. (Lindley, Vegetable Kingdom.)</td>

<td>RHODIZITE</td>
<td>A Mineral resembling Boracite [Bason] in its crystals, but it tinges the blow-pipe flame deep red. It occurs with the Red Tourmaline of Siberia. (Dana.)</td>
</tr>
<tr>
<td>RHODAMMONIAE</td>
<td>An order of Algae, consisting of purplish or blood-red Sea-Weeds, with an expanded or filiform inarticulate frond, composed of polygonal cells, occasionally traversed by a fibrous axis; superficial cells minute, irregularly parted, or rarely disposed in filamentous series; fructification in acropetal clusters, or frequently in the form of a sphere, or with a more or less bulbose or hemispherical, imperfect, containing beneath a thick pericarp a mass of spores affixed to a central placenta. The root is disc-like or branched, sometimes much matted; frond in habit and colour, either leafy or filiform, and much branched, never articulate; in some an intense crimson, in others brown-red or purple; usually growing somewhat darker in drying. The species are widely dispersed; all our genera having representatives in the Northern Hemisphere. The species are found in South America, or South-Western. It is often used for the purpose of making jellies and blanccmanges. (Harvey, British Algae.)</td>
</tr>
<tr>
<td>RHODIANTHUS, RHODIANTHUS</td>
<td>[Flameliola]</td>
</tr>
<tr>
<td>RHYNCHITES</td>
<td>[Wawari.]</td>
</tr>
</tbody>
</table>

Some of the natural order of moss-like Plants or Herbs, inhabiting mud or water, swimming or floating, usually annual; their leaves and stems blended into a frond of a cellular structure, creeping, green or purple underneath, with a distinct epidermis, and a cavity of air-passages beneath it in some species. These plants form a plain transition from Thallogens to Acrogea. Their spores are collected in large numbers within organs resembling the pistils of Phanogamous Plants. They are slender, sword-shaped, and formed into a ring, or more distinctly formed with stomates for breathing. The genus Duriaus is regarded as forming the nearest transition to Liverworts. It fructifies under water, which is very seldom the case with the other Crystal-Worts. Of this order several noteworthy types have been observed in Europe, and the remainder in various parts of the world. Several species in North America, the Cape of Good Hope, and Brasil, appear to be very similar to those of Europe. They are 16 genera and 59 species.

RINGWOOD, Hampshire, a market town, and the seat of a Poor-Law Union, in the parish of Ringwood, is situated on the left bank of the river Avon, in 50° 50' N. lat., 1° 47' W. long., distant 27 miles S.W. from Winchester, 92 miles S.W. by W. from London, and 159 miles by road, and 104 S. by the nearest line of South-Western railway. The population of Ringwood parish in 1851 was 3938. The living is a vicarage in the archdeaconry and diocese of Winchester. Ringwood Poor Law Union contains five parishes and townships, with an area of 18,432 acres, and a population in 1851 of 5446. The town is lighted with gas. The manufacture of thread and woollen gloves employs some of the inhabitants. The chancel and transepts of the parish church appear to have been erected about 1290; the nave and the tower are more recent. There are chapels for Wesleyan Methodists, Independents, and Unitarians, and National schools. There is an excellent corn-market, held every Wednesday. Fairs for horses and cattle are held on July 10th and December 11th. Ringwood is 1 mile S.E. of RINGWOOD STATION, one of the most eminent of the writers of the newspaper press in London, was a native of Scotland, and was born in 1787. Of the history of his boyhood little is known. He was probably born in Leith or in Dundee, and he availed himself of the advantages afforded by the grammar-schools of Scotland to acquire a well-grounded education. His first known entry into public life was as an editor of the 'Dundee Advertiser,' a weekly newspaper, somewhere about or a little before 1813. In this paper he at once evinced those remarkable powers of condensation and arrangement by which his after labours were distinguished. The paper advocated liberal, or rather the Whig, principles of the day, at that time by no means generally received in Scotland, though somewhat more favoured in Dundee than elsewhere. In this period he made no secret of the talent he displayed not only ensured the popularity and success of the newspaper, but procured him the support and friendship of many of the leaders of the Whig party in Scotland. As editor he was the assailant of the corruptions of the clergy, and zealous in the cause of the improvement of the burgh schools; for the extension of habour accommodation; and the expositor of fiscal mismanagement. About 1826 his connection with the 'Dundee Advertiser' was dissolved, he having decided to associate himself with various very serious schemes. Rhoditis is an ill-defined genus, and will probably be divided into several distinct genera. Many of the species, especially of the section Calophylla, are among the most splendidly coloured of crimson and carmine Algae. Others, as R. Hombroniana, R. Rubra, R. Aulis, and R. alba, are of a deep purple. Some of them, like the sobe duels of our coasts, R. palmaria, have often as much of brown as of purple in their attire. Many of the Rhodymeniaceae are valuable in an economic sense.

R. palmata, the Duke of our coasts, is collected largely in Scotland and Ireland, and forms an important article of diet. Many of the Gracilariaceae are largely used in the East as ingredients of Balm, and jellies. They are also as substitutes for Bicarbonate of Soda. One of them, O. spinosa, is the Agar Agar of the Chinese, and is largely collected both for culinary purposes and as a component part of some of the strongest Chinese gins. It has recently been imported into England, and is occasionally used instead of carrageen moss in making jellies and blanccmanges.
realising his notion of what a newspaper should be; and no man ever worked harder, more conscientiously, or more independently to effect his object. We have already noticed his faculty of arrangement, which he thoroughly carried out in ‘The Spectator.’ Besides writing on a multiplicity of subjects himself, he gathered cases and made a nest of the well qualified and distinguished men as contributors; but in most cases he suggested the subject, and in all he critically examined every one of their productions before they appeared in print. He was a supporter, through the paper, of all the great causes to which he was attached, and of the principles of its establishment, and probably few newspapers have had so much influence in forming opinions, particularly among the more highly educated class, as ‘The Spectator.’ The caution with which opinions were expressed; the avoidance of contradiction and opposition to himself; the recognition of objections or defects in matters where an approval was given of the whole; though sometimes seeming to give an air of coldness to his judgments, and occasionally even of indecision, aided the influence, by a quiet influence. Thirty years he continued this laborious and useful life up to within a month of his death, which occurred on April 22, 1758.

RIOJA, LA. one of the provinces of the Argentine Federation, extends the country beyond the Gran Chaco, Salina and the Andes, and extends from north to south from 28° to 31° S. lat. It is bounded S. by the provinces of San Juan and San Luis, E. by Cordova, N.E. and N. by Catamarca, and W. by the republic of Chili. The area is about 658,000 square miles. The population is variously estimated at 15,000 to 25,000.

The country is described generally under PLATA, LA. STATES OP. It consists of a narrow strip of cultivable land along the river base, with a series of vast, flat and round valleys of Famatina and Guandacol, and a pastoral tract extending round the southern extremity of the Sierra de Velasco. Only the northern districts of the country east of the Sierra Famatina are fit for agriculture. The province is by far the most easily accessible from intercourse with the more civilized parts of the Confederation. The roads leading to La Rioja are mere circuitous paths, hardly passable by mules, and the country is altogether in the most backward condition. The province is divided into four departments—Arango, Famatina, Guandacol, and the Llachas. Arango lies east of the Sierra de Velasco, and produces wheat, maize, and cotton; but its principal wealth is its vineyards. From 7000 to 10,000 barrels, of 16 gallons each, of a strong sweet wine, and about 3000 barrels of brandy are annually made, nearly the whole of which is exported to Cordova and the neighbouring provinces. The capital, La Rioja, is also that of the whole province. Famatina lies to the west of Arango, between the Sierra de Velasco and the Sierra Famatina. It contains rice, maize, and barley, and annually makes about 6000 barrels of wine annually. This department takes its name from the Sierra Famatina, celebrated for its mineral wealth. The silver-mines of Famatina are very rich, but the remoteness and inclemency of their situation—they being above the line of vegetation, and only accessible by difficult mountain-paths—have hitherto prevented them from being worked except on a small scale. The capital, Chilette, is a place of no importance. Golite prevails to a fearful extent in the valley of Famatina. Guandacol lies between the Sierra Famatina and the Andes, and produces very rich crops of wheat. It is thinly inhabited, and chiefly by aborigines, who hunt the vicuña in the adjacent mountains. The wool of the vicuña is the only article of export. Guandacol, the northern part of which is occupied by a detach of the British, consists chiefly of a desert plain, containing a great number of grisy cases, on which there are numerous cattle-farms. About 20,000 head of cattle are annually reared. Like the other provinces of the Argentine Confederation, La Rioja is governed by a governor appointed by the central government. The state government is nominally vested in a governor and municipal junta of five members. La Rioja, the capital of the state, is situated at the foot of the Sierras Famatina and Guandacol. It contains some substantial houses, a few public buildings, the only school in the province, and about 3000 inhabitants.

RIPLEY, [Yorkshire].

ROCCAMBOLO, [Alias].

ROCELLIC ACID. [Chemistry, S. 1.]

ROCHEA (named after La Roche, a French Botanist), a genus of Plantae belonging to the natural order Crossosomata. It has a 5-lobed calyx; petals 6, united into a pappose hypophyllous corolline, with a short tube, equal in length to the spreading limb or shorter than it; stamens 5, alternating with the petals, a little exserted; glands and carpels 5. The species are feebly simple, erect shrubs. The leaves are decussate, the flowers white, with petal-like bracts. The petals are disposed in terminal corymbs, without any bracts. A large number of the species are cultivated in our gardens and greenhouses.

ROGERS, SAMUEL, was born the 30th of July 1703, at Newington Green, a suburb of London. His father, who was a Dissenter, and much respected by the Dissenters of London, was a banker by profession; and the poet, after a careful private education, was placed, when yet a lad, in the banking-house to learn the business prior to his becoming a merchant. In 1718 he was graduated at the University of Wilkes calling at the banking-house to solicit his father's vote, and, as his father was out, shaking hands with him as his father's representative. From a very early period, the future poet exhibited a taste for letters, and he used his first determination towards poetry from the effect produced upon him by reading Beattie's 'Minstrel' when a mere boy. His admiration of literature and literary men led him, while still a clerk in his father's bank, to meditate a call on Johnathan Swift, the great philosopher and poet. On one occasion, with a young friend, he went to Johnson's house in Bolt Court bent on accomplishing the object, but his courage failed him when he had his hand on the knocker. It was in 1765—two years after Johnson's death—that Rogers, then in his twenty-sixth year, went with his book, The Poems, to the bank and house of Dr. Johnson, and there placed it under the title of 'An Ode to Superstition, and some other Poems.' The date is important. 'The commencement of a new era in British Poetry,' says a critic, 'dates almost exclusively from this year.' In 1765, there had been manifestations of a new poetic spirit, different from that of the poetry of the 18th century as a whole, and more particularly from that of Dr. Johnson, Hayley, and the Della Crusca, who represented the poetry of the 18th century in common. In 1765, Rogers, first of all English poets, published his Library in 1761; and Cowper had made his first distinct appearance as a poet in 1761, when he was already in his fifty-second year. Crabbe's Village was published in 1763, and Cowper first made an effective impression by the publication of his second volume, including his Task, in 1765. Thus Rogers was heard of as a poet almost at the same time as Crabbe and Cowper. But more exactly contemporary with Rogers than either Crabbe or Cowper, was Robert Burns, whose shade brightens up the landscape, overshadowed as it was by that very year, 1765, which saw Rogers's 'ASIM in an author.' In short, Rogers's first appearance as a poet coincides with the opening of that era in our literature in which we still are, and of which Rogers himself is one of the minor stars.

Rogers was a great man as a poet. He lived in France, where he saw Condorcet and many other men after wards celebrated in the French Revolution. He also visited Scotland, where he saw Adam Smith, Dr. Robertson, and other celebrities. In 1762 he published his 'Pleasures of Memory,' by which, and by a subsequent volume containing 'An Epistle to a Friend and other Poems,' published in 1766, he "established his place among the men of letters who adored Great Britain in the closing decade of the last century." During the next fourteen years he gave nothing new to the world, either to increase or to mar his reputation. It was during this long interval of silence that he retired from his hereditary business as a banker (though with an income still derived from the bank, and with the nominal character of a partner) to study the resources of his ample wealth, a leisure absolutely at the command of his private tastes. "The house of Rogers in St. James's-place," it is said, "became a little paradise of the beautiful, where, amid pictures and other objects of art, collected with care and arranged with taste, the habits of the nobleman and statesman prevailed, and kept up among his contemporaries a character in which something of the Horace was blended with something of the Mincus. As he had known Fox, and Horne Tooke, opposite political sentiments, and men of the highest talent and taste, and others of the eminent men of the former generation, he gathered round his table the political and social, and literary and dramatic celebrities who had succeeded them—Wordsworth, Scott, Byron, Coleridge, Mackintosh, Southey, Welington, Chatterey, &c, &c. His own political sentiments were those of moderate Whiggism, but this did not prevent men of all parties from being his guests."
In 1812, Rogers, when his muse seemed dead, added to a remarkable velocity of his years, the temperament entitled "Columbus." He was then in his fifty years. In 1814 his "Jacqueline" was published in conjunction with Byron's "Lara," this being the period of the height of the intimacy between the two so dissimilar poets. "Composed with the same descriptive and poetic passion, and with the same degree of smoothness," says the writer of a sketch of his life, "his Human Life" appeared in 1819. Finally, as the last and much the longest of his productions, came his "Italy," the first part of which was published in 1822, in the poet's ninety-third year. His work, in which, he contributed the author's care, at an expense of 10,000/., by Stothard, Prout, and Turner, did not appear till 1836. With the preparation of this exquisite book his literary career may be said to have come to a close; the rest were occasional copies of verses at the rate of a copula a week; and some of those trifles, including one written as late as his ninety-first year, are preserved in his collected works. But on the whole it was in his character as a superannuated poet, living on the repudiation of his past performances, drawing the artists and wits, and men of rank of a more modern age around him, and entertaining them with his caustic talk, and his reminiscences of the notable persons and events of former days, that he figured in a second portion of London life during the last years of his existence." The longevity of the poet was, indeed, one of the sources of the public interest felt for him in his later life. Always fond of open air exercise and of going to public exhibitions, he might be seen strolling about one of his still intact houses, or holding a few of his annual fays of an accident the streets at last disabled him from walking out; but the extraordinary tenacity of his constitution enabled him to recover from it, when a younger man might have died. It was not till the 10th of December 1856, when he was in his ninety-third year, and had for many years been the literary patriarch of his country, that he departed this life. Wordsworth and many other friends who had been born after him, and had attained old age in his view, had preceded him, and left him alone among a generation of juniors.

Rogers will be remembered partly for his poetry, and partly from the peculiar connection in which he stood, in virtue both of his longevity and his social position and habits, with the miscellaneous phenomena, and especially with the art and literature of his time. His poetry is of the highly finished and tasteful rather than the powerful kind. "We have in his works," says a critic, "a classic and graceful beauty; no slovenly or common lines; fine cabinet pictures of soft and mellow lustre, and occasionally trains of thought and association that awaken or recall tender and heroic feelings." His relations to his time was less of active influence than those of shrewd observation and interesting reminiscences. A good deal is said of his "Table Talk," published since his death, by his friend Mr. Dyce. ROMEINE. [MINERALOGY, S.1.] ROSEWOOD. [TRIPTOLEMUM, S.2.] ROYAL HOLLAND SHIP- WRECK. In his essay, "The Commerce of the Seas," J. B. Ross, Rear-Admiral Sir John, Knight, was born June 24, 1777, at Balaarock, Wigtonshire, Scotland. He was the fourth son of the Rev. Andrew Ross, of Balaarock, minister of the parish of Inch. He entered the navy as a first-class volunteer November 11, 1786, on board the Peal, 32 guns, and served in the Mediterranean till 1789. From November 7, 1790 till 1791, he served on board the Impregnable, 96 guns, in the English Channel. After being some years in the Navy, he went to sea in 1799, as a midshipman on board the Wessel, 20 guns, in the year which that year formed part of the expedition to the coast of Holland. After having served on board several other king's ships, he received his commission as lieutenant, March 13, 1805. While attached to the Juno, 18 guns, in 1806, it was severely wounded in four places in cutting out a Spanish vessel under the batteries of Bilbao, for which, in 1808, he was granted a pension of 382/. a year, increased in 1815 to 1500/. a year. In 1812 he was ranked of commander February 1, 1812, and was appointed to the Bridgeport, 28 guns, with orders to proceed in her Southward to other vessels, till the termination of the war in 1815, during which period he performed several valuable services. He married his first wife in 1816. He was stationed in the Mediterranean in 1816, and in the same year was promoted to the rank of commander, and in 1817, he took a letter from Sir George Hope, one of the Lords of the Admiralty, informing him that two ships were to be sent out, to "ascertain the existence or non-existence of the new species of pecten," and inquiring whether he was disposed to undertake the command of the expedition. Having expressed his willingness to do so, he was directed to repair to London, where he arrived on the 30th of December. On the 14th of January 1816, he received his commission as commander of the Grace Darling, 68 guns, under the command of Captain W. E. Parry being appointed to the command of the Alexander, 252 tons. The two ships departed from the Thames, April 25, 1818. They sailed up the eastern side of Davis's Strait and Baffin's Bay, and returned through the Arctic and North-West Passage. The Alexander, with a total of 10,000 tons, was a considerable distance behind the Isabellas. Parry however and his officers could see no mountains, and were greatly surprised and disappointed when the Isabella turned her head eastwards, and gave the signals for Alexander to follow the example. Ross named the supposed high land the Croker Mountains, and has laid them down in his chart as a continuous chain closing up the bottom of the supposed bay. This was a mistake, as Parry believed at the time that he had been the first to see the entrance to Davis's Strait. The ships arrived in the Thames on the 14th of November, 1818. On the 7th of December, the same year, Ross was advanced to the rank of post-captain. Ross was in command of the, Alexander, 1819, under the Orders of the Admiralty, in his Majesty's ship Isabella and Alexander, for the purpose of exploring Baffin's Bay, and entering into the Probability of a North-West Passage, 21° 40' N. 1819.

After the unsuccessful attempt of Captain Parry to reach the north pole, in 1827, Captain Ross submitted to the Lords of the Admiralty and to the Lord High Admiral the plan of another voyage of discovery to the Arctic seas. The government having granted him a small sum, a steam-ship was equipped at the expense of Mr. Felix Booth (afterwards Sir Felix Booth), then sheriff of London. The ship was named the Victory, and was fitted with an engine, invented and patented by Messrs. Brathwaite and Ericsson, which proved to be so bad as to be almost useless. Commander James Clark Ross, nephew of Captain Ross, was chosen as second in command. They had an attendant vessel of 16 tons hulk, granted to them by the Admiralty, named the Kruse eastern. The Victory, with its attendant, left the Thames May 24, 1839, and, using partly her sails, and partly her "execrable machinery," as Ross calls it, entered Davis's Straits, July 5. Captain Ross expected to find a north-west passage through Prince Regent Inlet, which he knew to be a passage, and to proceed up Baffin's Fury, which had been wrecked. The Victory and the Kruse eastern entered the Inlet on the 12th of August, and on the following day discovered the wreck of the Fury. They afterwards proceeded up the Inlet, and on the 8th of October were frozen in at the narrow front, west side of the Gulf of Boothia. They were not released from the ice till the 17th of September 1839, and were able to advance but a very short distance before they were again frozen in on the 31st of October. On the 20th of August 1831, the Victory was again released from the ice, but on the 20th of September was forced by the pressure into another harbour. In April 1832 the soldiers commenced carrying north aboard the boats, and a few men out of the ship, and an additional 292 tons of stores were finally abandoned. Captain Ross, in his journal observes, "In the evening I took my own aide de camp's observation. It was the first vessel that I had ever been obliged to abandon, after having been eleven months in a period of forty-two years." Some of the crew had died, and the rest were much weakened, but they struggled on till the 15th of August 1833, when the ice broke, and they were enabled to set sail in the boats. On the 25th of August, when near the point of land to the northward of the ship, the Isabellas, which was out on a whaling voyage. The mate in command of a boat that was sent to them, Captain Ross asking him the name of the vessel, said it was the Isabellas, Captain Ross, met by the vessel's master, and stated that I was the identical man in question, and my people were the crew of the Victory." Unshaven as they all were, dirty, dressed in tattered skins, and wasted almost
to the bones, the man doubted the statement, and said that Captain Ross had been dead two years. He was easily convinced of his error, and they were received on board the Isabella, with the yards and rigging manned, and with three hearty cheers. The Isabella arrived at Hull on the 18th of
September, 1833, and on the 19th Captain Ross reached London by steamer.

While the ships were frozen up in the Gulf of Boothia, many observations and surveys were made by Commander Ross, and some by Captain Ross himself, of the coasts and country which they named Boothia Felix. During one of these journeys Commander Ross discovered, June 1, 1831, a species of a new animal, which he named Leukenhoekia n.sp., now known by its name of 70° 6' 37" N. lat., 96° 49' 45" W. long., where the dripping needle indicated a dip of 89° 59', or within one minute of the vertical.

On the 24th of December 1834, Captain Ross received the honour of knighthood, together with the companionship of the Bath. Many other honours and several rewards were conferred upon him. In 1835 he published a 'Narrative of a Second Voyage in Search of a North-West Passage, and of a Residence in Arctic Regions during the years 1829, 1830, 1831, 1832, 1833, by Sir John Ross, C.B., &c., Captain in the Royal Navy, including the Reports of Commander (now Captain) James Clarke Ross, R.N., F.R.S., F.L.S., &c., and the Discovery of the Northern Magnetic Pole,' 4to, which has been since published as 'Appendix to the Narrative,' &c., also in 4to, chiefly consisting of accounts of the Eskimaux, and of the zoology, the meteorology, and similar matters. On the 8th of March, 1839, Sir John Ross was appointed consul at Stockholm, which station he maintained until the 24th of December, 1840, when he went out in search of Sir John Franklin, in a small vessel of 90 tons, named the Felix, and remained one winter in the ice. The government lent him no assistance, and early in 1839 he wrote a pamphlet, in which he complained of his own treatment, and in the same pamphlet is entitled 'A Narrative of the Circumstances and Causes which led to the Failure of the Searching Expeditions sent by government and others for the Rescue of Sir John Franklin.'

Sir John Ross's first wife having died in 1832, he married a second, October 21, 1834. By his first wife he had issue one son, who is a magistrate at Cawpoor in Hindustan. Sir John Ross is the author of 'Letters to Sea-Officers,' 'Memoirs and Correspondence of Admiral Lord de Saumares,' &c.

ROSSIA, a genus of Cephalopoda Mollusca, named by Professor Owen in honour of Sir John Ross, who found one of the first specimens in the Arctic Sea. It belongs to the family Tethisida, and has a rounded or oval body, furnished on each side with a suborbicular fin; a large head, with eyes covered by a transparent scutum, and in the young: with a tentacle; with several small holes; arms ten, two tentacular and reticulate, elb. conicorous, flexible, small, and sub-biarticulate. There are five species, of which two are British, R. macromela and R. Ocest. These have been both taken in Ireland, and the latter also near Benchich, in the Isle of Wight.

ROTIFERA, Wheel-Animalcules, a class of animals placed by Ehrenberg among the Infusoria, under the name of Rotatoria. They have acquired these names on account of the apparent rotation of the discs of organelles which surround their minute bodies, and which are covered by cilia. These structures are very minute, and although some of the larger forms may be detected by the naked eye, their organisation can only be seen by the aid of the microscope. We are indebted to Leukenhoek for the discovery of their existence, and the first account of their structure and habits. In the 'Philosophical Transactions' for 1702, he gave an account of the discovery of what is now called Rotifer vulgaris, one of the most common forms of these animals. He afterwards described a species, R. ciliata, and so on.

Subsequent observers added to the discoveries of Leukenhoek, so that in 1834 Bory St. Vincent described 80 species. In 1838 Ehrenberg published his great work on the Infusoria, and there is little doubt that he described some species. Although classed by Ehrenberg with the Polycystres, their organisation is much higher and more complicated, and the only claim they appear to have to be classed together is the fact of their minute size. [Infusorial.]

The Rotifera are very widely diffused on the surface of the earth. They inhabit both fresh-water and the ocean, and are found in the cold, temperate, and tropical parts of the earth. Although capable of swimming freely, they are usually found near or attached to the leaves of plants. They are found constantly present in ponds and streams in which Ceratophyllum, Callitriche, Valiniera, and other fresh-water plants abound.

A curious point in their history, which first attracted the notice of Leukenhoek, is their power of retaining their vitality after having been more or less perfectly desiccated. This property is undoubtedly possessed by the ova of the lower animals, especially those which are called 'flagellate.' Other animals are generally possessed by animals of an organisation as high as the Rotifera. Professor Owen states that he has observed the revivification of one of these wheel-animalcules after having been kept four years in dry sand.

The Rotifera have usually an elongated form, although some of them are nearly as broad as they are long. In most instances they are covered with a lorica or double envelope, the outer layer of which is often of a horny consistence. Some of them build for themselves a little case, or tube, in which they live, but this must not be confounded with their proper envelope. When the lorica is soft the animal has considerable power of elongating and contracting its body, as seen in Rotifer vulgaris. Many of the species are further provided with two to eight pairs of small feet, or tentacles, which is similar to that of the sea-beetle. These organs are furnished with finer hairs, or pincer-like organs, to enable them to remain stationary whilst feeding. Those which form tubes are usually fixed.

The rotatory organs, or wheels, are fleshy retractile lobes, covered with vibratile cilia, and are capable of being contracted on the inner face of the lorica, in the manner of a muscular system. Muscular bands are observed attached to the tegumentary system, and also to that part of the digestive system connected with the rotatory organs. The spines of these muscles have been observed to present the same characteristic of voluntary muscles.

The digestive system consists of a month, jaws, frequently a dilatation which may be regarded as a stomach, and an intestinal tube which has an as and orifice. The jaws generally consist of three or more lobes, to which are added a pair of jaws, which is characteristic of voluntary muscles.

The digestive system consists of a month, jaws, frequently a dilatation which may be regarded as a stomach, and an intestinal tube which has an as and orifice. The jaws generally consist of three or more lobes, to which are added a pair of jaws, which is characteristic of voluntary muscles.

All observers agree that the Rotifera possess a nervous system, which presents itself in the form of a pair of cephalic ganglia, from which proceed nervous filaments. The extent of which we know in the nervous ganglia. For further inquiry. The red spots which Ehrenberg calls eyes are subject to considerable variations in appearance. Mr. Huxley says he observed them in young Lacinulinae, but not in adult individuals.

The existence of senses in a species of Notomata has been clearly made out by Mr. Brightwell of Norwich. The male however is much smaller and less developed than the female. All observers agree that the parts to which Ehrenberg has assigned the functions of male organs are not so certain. Caudal ciliated organs, which are described in this species, are attached to the cilia, but their nature is doubted by other observers. Mr. Huxley describes in Lacinulinae certain "vascular thickenings," which he suggests have been previously mistaken for organs of locomotion. Other species have similar organs out in most of the species. The ova are of two kinds. Mr. Huxley says in Lacinulinae they consist, first, of bodies which resemble true ova in their origin and subsequent development, and which possess only a single vitelline membrane; second, of bodies half as large again as the foregoing.
which resemble the epithillum of *Daphnia*: like it they have altogether three investments, and which do not resemble true ova either in their origin or subsequent development; while this has not been the subject of much discussion. Dr. Grant was one of the earliest writers to take them out of the *Radiata*, and place them amongst *Articulata*. The relation of such forms as *Stephanoceros* to the Ciliophoracea Poyla is very evident. In his "Memoir on Decapoda," Mr. Huxley gives his reasons for regarding these creatures as permanent larval-forms of *Echinoderma*. After referring to the various forms of Rotifers, and their homologous organs, he thus concludes:

"We may say, therefore, that the Rotifers are organised upon the plan of an Annellid larva, which loses its original symmetry by the unequal development of various regions, and especially by that of the principal ciliated cirque or trochal band; and it is curious to remark that, so far as the class can be considered a group (out of 1851), the distinct forms belong to the latter of the two modifications of the type which have been described, while the monocious forms belong to the former."

"It is in circumstances which seem to me to throw so clear a light upon the position of the Rotifer in the animal series. In a Report in which I have endeavoured to harmonise the researches of Professor Müller upon the Echinoderms, 'Annals of Natural History,' 1831, I have shown that the same proposition holds good of the latter in their larval state, and hence I do not hesitate to draw the conclusion (which at first sounds somewhat startling) that the Rotifers are the permanent forms of Echinoderm larvae, and hold the same relation to the Echinoderms that the Hydroid larvae hold to the Medusæ, or that Appendicularia holds to the Ascidians."

"The larva of a *Sipunculus* might be taken for one of the Rotifers; that of *Ophiura* is essentially similar to *Stephanoceros*; that of Asterias resembles Lacinularia or Melicerta. The pre-trochal processes of the Asterid larve Brachioaria are equivalent to those of *Brachiuran*.

"Again, the larve of some Asterid forms and of Comata are as much articulated as any Rotifer."

"It must, I think, have struck all who have studied the Echinoderms, that while their higher forms, such as *Echinus* and *Sipunculus*, tend clearly towards the dichotomous *Aaena-

"Now, if the view I have proponned be correct, the Rotifer furnishes this wanting link, and connect the Echinoderms with the *Nemertidea* and Nematoidea worms."

"At the same time it helps to justify that breaking up of the class *Radiata* of Cuvier, which I have ventured to propose elsewhere, by showing that the Rotifers are not 'radiate' animals, but present a modification of the Annellid type—belong, in fact, to what I have called the *Annuloida*, and form the lowest step of the Echinoderm division of that sub-kingdom."

Dr. Leydig, in a paper in the "Zeitschrift für Wissenschaftliche Zoologie," vol. vi., on the other hand, regards the relations of Rotifers as much more with the Crustacea than with the worms. The points of resemblance to which he draws attention are:

1. Their external figure and hard tegument, which more nearly resembles the carapace of the Crustacea than the rings of the Articulata.
2. Their muscular structure, which resembles that of many Crustacea.
3. Their nervous system resembles that of many Entomotrocha, as *Daphnia*.
4. The alimentary canal resembles that of *Daphnia*.
5. The resemblance in the character of their ova, the Entomotrocha having two kinds of ova, as the Rotifer.
6. The development of Rotifer and Entomotrocha Crustacea correspond.

Leydig composes a very able paper by proposing to call the Rotifer Ciliated Crustacea.

With regard to the arrangement of the Rotifers, that of Ehrenberg, which is exceedingly defective, has been given under *Rotauro*. From the previous observations on structure, we will see that this arrangement is open to many objections.

Dujardin, who was one of the earliest observers that pointed out the defects of Ehrenberg's arrangement, has proposed the following:

**Order I. Systolides.** Fixed by a pedicel.

2. *Stephanoceros* Eichhorni, Ehr.; *Stephanoceros*.
3. *Rotifera*.
4. *Lacinularia*.
5. *Echinodermata*

Leydig has proposed an arrangement of his own, which is preferable to either of the above.

**Ciliooctocysta.**

Animals with a jointed body and a ciliary apparatus at the cephalic extremity. The nervous system consisting of a cerebral ganglion considered the larval feat of it. Digestive and respiratory systems much developed. No heart or blood-vessels. Sexes separate. The female produces 'summer-ova' and 'winter-ova'; many undergoing metamorphosis.

A. Figure between clavate and cylindrical.

1. With elongated transversely-ribbed attached Foot.
2. *Floscularia* (Echinotassa), Ehrenberg; *F. ornata*, Ehr.; *F. appendiculata*, n. s.
4. The larval forms of *Sipunculus* (Ehr.)
5. *Sipunculus* (Ehr.)
6. *Lacinularia* (Ehr.)
8. *Melicerta* (Ehr.)

II. With elongated jointed foot, retractile, like a telescope.
1. *Cellodina elegans*, Ehr.; var. C. rosea, Parry; *C. ornata*, Parry.
2. *Hydraea cornyera*, Ehr.
3. *Sipunculus* (Ehr.)
5. *Actinurus* neptunus, Ehr.
7. *Philodina* (Ehr.).
8. *Melicerta* (Ehr.)

II. With elongated jointed foot, retractile. Foot.
1. *Cellodina elegans*, Ehr.; var. C. rosea, Parry; *C. ornata*, Parry.
2. *Hydraea cornyera*, Ehr.
3. *Sipunculus* (Ehr.)
5. *Actinurus* neptunus, Ehr.
7. *Philodina* (Ehr.).
8. *Melicerta* (Ehr.)

III. With elongated jointed foot, non-retractile Foot.
1. *Cellodina elegans*, Ehr.; var. C. rosea, Parry; *C. ornata*, Parry.
2. *Hydraea cornyera*, Ehr.
3. *Sipunculus* (Ehr.)
5. *Actinurus* neptunus, Ehr.
7. *Philodina* (Ehr.).
8. *Melicerta* (Ehr.)

IV. With a short Foot and long Pedal Foot.
1. *Nemotoma* (N. *tartist*, N. *longifis*, Ehr.
2. *Monobius* cornu, Ehr.
3. *Sipunculus* (Ehr.)
5. *Microdon* (Ehr.)

V. With short Foot and Pedal Foot, which are of equal length or somewhat shorter or longer than the former.
1. *Hydatina* senta, H. *brachydactyla*, Ehr.
4. *Rotifer*, (probably not a *Furcularia*, but a *Nemotoma*).
6. *Sipunculus* (Ehr.)
8. *Sipunculus* (Ehr.)

**Systolides.—Fixed by a pedicel.**

Family 1. *Floscularia*.

Family 2. *Melicertas*.

Family 3. *Brachionians*.

Family 4. *Furcularias*.

Family 5. *Albertarians*.

Family 7. *Tardigrades*.

Family 8. *Cellodina*.

Family 9. *Sipunculida*.
cattina, D. canina, D. caputata, D. candida, Ehr.
8. Rattalus lunaris, Ehr.
10. Tripalpia, Ehr. and N. and Ehr.
13. Theura vernalis, T. uncinatus, Ehr.

Note.—Huxley’s genus, Endopelma hydatina, is the name of Huxley in 1810 and his Notes on Normania, over to the genus Huxleyi, which latter genus however is placed far more correctly under the genus Brachthous than under Normania. *Dilegna* granulata, Weise, lastly, is the male of *D. cattina*, Ehr.

VI. Without Foot. Insecta.

Includes the A. aevula, found by Dujardin in the abdominal cavity of the ieworm, and in the intestines of the *Locietina*; and *A. coculina* discovered by Schultz in the intestine of *Naiu larilicata*.

B. Figure saciform.

I. Foot short.
1. Normanata diastolata, K. muratana, K. sinra, Ehr.
2. Dilegna laxatia, Ehr.

II. Foot absent.
1. Normanota Angios, Dalrymple; N. Sieboldii, Ehr.
2. Polyarthria platypoda, Ehr.
3. Triarthria longiseta, T. notica, Ehr.
4. Ascomorpha hodoreta, Pery; A. Germanica, Ehr.

C. Figure compressed.

a. Compressed from above downward.

I. With a foot.
1. Euclanis triquetra, E. hornemanni, E. una, E. macrura, E. dilatata, E. Lynceus, Ehr.; E. ensetata, n. sp.; E. biocinrinata, n. sp. (E.; Ehr.
2. Lepadula ovalis, L. emarginata, L. sulcata, Ehr.
5. Staknapa lamellaris, S. mutica, S. cirrata, Ehr. (Dujardin says that S. mutica is Lepadolla.)
8. Notus quadrivoinea, Ehr.

II. Foot absent.
1. Anura quadridentata, A. squamilla, A. falcu-
2. A. acicularis, A. hornemanni, A. serira, A.
3. A. nema, A. acuminata, A. flacica, A. stipa-
5. Laterally compressed.
6. Salpingo muetana, S. spinigeria, S. ventralis,
7. A. acicularis, A. brenniana, A. bicorneta, Ehr.
8. Mastigocera carinata, Ehr.
9. Monura coluris, M. dulcis, Ehr.

ROY

India. He several times read papers on the cultivation of tea and cotton in India at the meetings of the British Association for the Advancement of Science. His activity at those meetings led to his appointment for a short time as co-secretary with General Sabine of that association. In 1840 he published an Essay on the Productive Resources of India. In 1845 he also published a volume on 'The Fibrous Plants of India,' pointing out those which could be made more especially available for the manufactures of Great Britain. He took an active part in the Great Exhibition of 1851, especially in arranging the East Indian department. He was a Fellow of the Royal and Linnean societies, and held an appointment in London in connection with the East India Company. He died January 2, 1856, at his residence, Heathfield Lodge, Middlesex.

In respect to race, the Baron gives the following approximations in round numbers:
1. Slavonic races—Russians, 49,000,000; Poles, 6,500,000; Lithuanians and Lettish, 2,000,000; Bulgarians and Illyrians, 500,000; total, 58,500,000.
2. Other races—Germans, 650,000; Dacic Romans (Wallach), 750,000; Tschudes, 3,400,000; Tartars, 2,150,000; Mongols, 250,000; Munahun, 100,000; Hyperboreans, 200,000; Caucasian tribes, 2,750,000; Greeks, 70,000; Jews, 1,650,000; Gipisses, 50,000; Miscellaneous, 50,000; total, 19,000,000.

The revenues of Russia, of which we have no recent return, amount to about 360,000,000 silver rubles, of which 45,500,000 silver rubles were derived from the domains of the crown. The debt in January, 1856, amounted to 1,042,466,179 silver rubles. (The value of the silver rouble is about 3.4 S.)

The state of the army and navy of Russia, in the year 1857, is given in the article MILITARY AND NAVAL FORCES, S. 2.

RUSTCHUK, a fortified town in Bulgaria, capital of an eyalet in European Turkey, is situated near the right bank of the Danube, about 40 feet above the level of the river, 40 miles S. from Bucharest, and has a population variously estimated at from 30,000 to 40,000. The Danube opposite Rustchuk is nearly two miles wide, but its surface is broken by a number of islets and shallows, and the banks are low. From a distance Rustchuk has an agreeable appearance, with its white chimneys and graceful minarets, rising up from among the foliage of extensive orchards. This impression however is removed by a view of the interior, which presents dirty ill-paved streets, flanked by low wooden houses, most of which stand in little courts or gardens. The Pasha's khan, or palace, and the mosque, are the only buildings worth notice. The town has baths, a bazaar, and about 3000 houses; it has also some trade with Vienna in cloth, indigo, corn, wine, &c. A harbour for river craft is formed below the town by a small recess of the river, which is sheltered towards the north-east by a cape crowned by a bastioned citadel. Rustchuk is commanded by heights to the south-west, on which five detached bastioned earth-works have been recently thrown up. The town itself is surrounded by an earthen rampart, which presents eight bastioned fronts, revetted half-way up with masonry, and surrounded by a moat and counterscarp. The front towards the river is irregularly fortified. The Russians took Rustchuk after enormous losses of men in 1811; it opened its gates to them in the invasion of 1858. The fortified enceinte of Rustchuk measures four miles. On the left or Wallachian bank of the Danube, opposite to Rustchuk, is Giurgevo, which was originally the fortified tête-de-pont to Rustchuk. Its defences were raised in carrying out the treaty of Adrianople, but have been since repaired. A ferry connects the two places. A tall clock-tower stands in the principal square. One of the islands in the Danube is fortified. A pentagonal fort built with stone defends the harbour. Beyond this fort the town of Giurgevo is built; its enceinte presents a semi-circle towards Wallachia. Giurgevo trades with Austria in the produce of the country, and has about 7000 inhabitants. In the wars between Russia and Turkey, Giurgevo has been frequently the scene of hard fighting between the two nations. The Russians took it in 1711, and completely defeated the Turks in the vicinity the same year; they took it again in 1810. The Russians occupied Giurgevo in 1824, and were defeated by the Turks under its walls on July 7 of that year.

RUTHEN. [Dobrudza, S.]
RYDE. [Wight, Isle of]
SABADILENA. [CHEMISTRY, S. 1.] SACCHARIC ACID. [CHEMISTRY, S. 1.] SACCHARITE, a Mineral resembling granular felspar, of a greenish-white colour, and with the constitution of Lodest. It is found in Siberia, and the north of America.

SACRAMENTO CITY, the capital of Sacramento County, State of California, United States of North America, is situated on the left bank of Sacramento River, at the confluence of American Fork, in 39° 34' N. lat., 121° 40' W. long., about 100 miles N.E. from San Francisco. The city was founded in the spring of 1849; in 1850 it contained 6820 inhabitants, of whom only 474 were females; and at the State Census in 1862 the population was above 10,000.

Sacramento City owes its origin to the discovery of gold, which so remarkably impetuous to California generally. It was on the south branch of American Fork, about 50 miles from Sacramento City, that gold was first discovered. The growth of the city was, from its foundation, remarkably rapid. In April 1849 there were only four houses on the site; in the following year it was laid out and regularly laid out of nearly 7000 inhabitants. The city stands in the midst of a fine farming country, and about 30 miles from the commencement of the gold diggings. Occupying a low site, it has been found necessary, in order to protect it from inundations, to which it is liable in the rainy season, to construct a levee along the bank of the river. The streets of the city cross each other at right angles; those running east and west are designated by the letters of the alphabet, and those running north and south by the numerals. Many of the streets are lined with oak and acamore trees, some of large size, imparting a considerable degree of picturesqueness to their general appearance. The city contains Episcopalian, Presbyterian, Catholic, and other churches, schools, numerous stores, above 150 eating saloons and hotels (some of which are of a very costly and splendid character), several steam-mills, and a few manufactories. Like San Francisco, Sacramento City has suffered severely from several very destructive fires; but the parts of the city which were destroyed have always been quickly rebuilt, and generally in an improved style. Several daily and weekly newspapers are published here. Regular daily communication is maintained with San Francisco by steam-boats.

SADDLEWORTH. [Yorkshire.]

SAQUINUS. [Saxon.] SAQUERUS, or SAGUES, a genus of Plants belonging to the family of Palmae. The leaves are pinnate; the flowers monoecious, with several spathes, but with numerous partial ones; the fruit hard, absciss, its surface divided into numeronous rhomboidal spaces. The species are natives of the islands of the Indian Archipelago, and yield sago.

S. Rumpfii, the true Sago-Palm, has the petioles and spathes unarmed. This plant furnishes most of the sago sent to Europe.

S. Rumphii has the petioles and spathes guarded by strong prickles. According to Martin, the sago yielded by this plant is used principally in India, and seldom exported.

SAINTE-Arnaud, Marechal Leroy DE, was born in Paris, of poor parents, on the 30th of August 1798. Having entered the Royal Body-Ordnance at the age of sixteen, he rose to the rank of sub-lieutenant in the infantry of the line in 1813. Owing to some youthful vagaries, he left the army shortly after, and embraced the theatrical profession, when he first performed at the subme Théâtre des Batignolles. In this capacity he returned to the army, and rose to the rank of major; but the revolution of July revived his taste for martial life; he returned to the army in 1831, and having entered the 64th regiment as sub-lieutenant, was made full lieutenant within six weeks. The insurrection of the partisans of the Deuchese de la Tregue, his brother, and the loss of the latter by the dread of earning the favourable notice of Marshal Bugeaud. He was subsequently appointed to the charge of the citadel of St. Blaye, where the Deuchese de Berri was confined—a post in itself, from the circumstances, somewhat painful to an honourable man, and his conduct in it incurred for him considerable odium.

In 1836 Saint-Arnaud was sent to join the army in Algiers, on the war with the Russians; he bore himself with much courage at the siege of Constantine, and received the decoration of the Legion of Honour. The brilliant courage he displayed in these campaigns obtained for him the rank of commandant of the 18th regiment of infantry in 1840, but his erratic disposition induced his removal from it to the 32nd in the following year. In 1842 he was created lieutenant-colonel; and in 1844, on the recommendation of Bugeaud, he became colonel of the 32nd regiment. During the next three years he was constantly in the field; his reputation increased, and he was made major-general in 1847. In 1850 he was appointed to command the province of Constantine, which was then in a very unsettled state; but he subdued the whole country within the year. In the early part of 1851 General Saint-Arnaud was despatched on an expedition against the Kabyles, which was entirely successful, and was considered one of the most brilliant campaigns of the French in Algeria. His little army did not amount to 7000 men, and with this he overran that rugged country, and in spite of a desperate resistance he conquered the whole province. This was the service which fixed upon him the attention of the President of the French Republic.

Saint-Arnaud returned to Paris in the autumn of 1851, as General of Division.Louis Napoleon at once took him into his confidence, giving him the command of the second division of the army of Paris immediately after his arrival, and then appointing him minister of war. He acted cordially with the French President; "Nothing," he wrote to his mother, November 19, 1851—"nothing at all, you understand, is wanting, but to go straight forward and be bold." In the famous coup d'état of the 2nd of December following he was the President's chief adviser and instrument. Honours now accumulated on him, he was made marshal of France, then a senator, and received the grand cross of the Legion of Honour in 1852. His health had gradually declined under so harassing a life; yet he so strongly solicited the command of the French army intended for the east, at the outbreak of the war with Russia, that his request was granted. The events of that war are so well known that we need not dwell upon them. It will be enough to say that Marshal Saint-Arnaud entered upon it with the utmost eagerness. He evidently felt that a splendid chance was afforded of professional distinction. For a time his impetuosity enabled him to bear up under his constantly-increasing malady. The landing in the Crimea, which he calls his favorite idea, he tried to the utmost to hasten forward; and fearing at last that his health was endangered, he instinctively returned to the peacefulness of his opinions of his colleagues. On the morning of September 20, 1854, Marshal Saint-Arnaud mounted his horse with great difficulty, and by the constant exercise of great spirit sustained all the fatigues of command during the battle of the Alma. He exhibited the same energy in his despatch after the victory, but the intensity of his feelings is only fully seen in his letters to his wife, published in the collection referred to below. But the effort proved too much for his remaining strength; his malady increased daily, and on the 27th he was obliged to embark on board the Berthollet to return to Constantinople. He died on the 29th of September, 1854, whilst yet on his passage.

The career of Marshal Saint-Arnaud, almost up to the outbreak of the Russian war, showed him too much in the light of a daring and not very scrupulous adventurer; and he did not live long enough, when a nobler field was opened to his ambition, to show whether he possessed the abilities of a great commander. In the literature of the period he was earlier, he exhibited the most brilliant and daring courage, combined with judgment and energy, devotion to his duty was never so strongly evinced as at the close of his career. Two volumes of his private letters have been published by his brother, 2 vols. 8vo. London, 1855, which, though exhibiting many suppressions, give much curious information respecting the last twenty-five years of his remarkable career.
SAINT HYACINTHE. [Canada, S. E.]

SALICARIA, a genus of Birds belonging to the family Sylviidae, and separated by Mr. Selby from the genera Locustella and Sylvia. "The rounded form of the tail," says Mr. Yarrell, "the outer feathers being much shorter than those in the middle, and the paridity of these birds to moist situations, may be considered as the chief distinguishing character, and the Red Warblers, appear to separate them from the Sylvian Warblers." There are four British species of this genus.

S. locustella, the Grasshopper Warbler, is so called from its very peculiar almost incessant cricket-like note. It comes to this country from the south, and appears about the middle of April, and departs in September. It is a shy bird, keeping at the bottom of a hedge, and creeping along more like a mouse than a bird. It feeds on small suails, slugs, and insects.

S. phragmitis, the Sedge-Warbler, Sedge-Bird, is found during the summer in thick patches of reeds orwillows, in marshes, or on the low sides of rivers, or on islands. Like the last, it is a summer visitor, arriving in April and leaving in September. While of Belgium first observed its power of imitating the notes of other birds, as well as of its occasionally singing at night. It measures 4½ inches, and is somewhat a l-is bird than the last. It is also called, the Willow Locustella. It is a rare bird in this country, but like the group to which it belongs, it frequents moist and shaded situations, among reeds and bushes, near water.

S. armata, the Reed-Warbler, the Night-Warbler, this little Warbler was found in company with the Sedge-Warbler, but is not so numerous in this country as that bird. It arrives here in April and departs in September. It sings usually in the day, but sometimes at night. The characteristic sound of the bird, the entire absence of the body while stripe over the ear-coverts, and the uniform colour of the whole of the upper surface of the bird of this bird, distinguish it from either the Grasshopper-Warbler or the Sedge-Warbler, both of which however it has manly habits in common.

SALTORES. [Antrim, S. E.]

SALVANDY, NARCISSE-ACHILLE, COUNT DE, was born, in the department of Gers, June 11, 1798, but was sent to Paris in early youth, and educated at the Lyceé Napoleon. He enlisted as a volunteer in 1812, and served with so much distinction during the campaigns of 1812-14, that on the 8th of April, 1814, the emperor bestowed upon him, with his own hands, the decoration of the Legion of Honour.

After the restoration of the Bonbons, in 1814, M. de Salvandy was made an officer of the royal household, and in March 1816, attained Louis XVIII. to the frontiers. About this time, in his twentysixth year, he began that long series of argumentative pamphlets, for which he afterwards became so celebrated, by the publication of two brochures, one called 'Mémoire sur les Griees et les Voix de la France,' the other 'Journal des Deux Chambres de Mai, 1816' he brought out 'La Coalition et la France,' in which he displayed considerable talent. It produced a great sensation in more than one court.

In 1823 he became a member of the conseil d'état, holding the office of Maire de Roquefaret. But he was incapable of submission to any control. The measure presented by M. Barthelemi, on the 'Loi des ELECTeurs,' appeared to him an organic change unfavourable to the constitution; he therefore published his 'Voes Politiques,' in which, regardless of place and emoluments, he fully described the nature of political parties, their power, influence, and objects. This act of independence was followed by several others, as the restored family wished to advance in their system of aggranements with public liberty, parti this, and the "Dangers de la situation presente," produced a rupture between him and the ministry.

In 1834 M. de Salvandy went to Spain, and shortly afterwards married Madame Chabert, the journal of whose interest was a work of more than usual length, "Don Alonzo, on L'Espagne," comprising a full account of the Peninsula, and its various political changes. It was in the course of the same year, 1834, that he began to write his well-known "Histoire des Conventions," the most complete yet produced. The work, which at that period were entitled 'Les Funérailles de Louis XVIII.,' and 'Le Nouveau Règne et l'Ancien Ministère,' recommending a course of constitutional policy to the electorate, and containing the discussions of the period of the "Journal des Debats," is the most complete and laboured of all his books, and other independent political writers, he steered a middle course between the opposite parties, and flattered neither of them. Ever constant to his principles, and equally averse to abridgment,
troy rule and anarchical divisions, he maintained for forty
two years the same moderate opinions of equity and justice.
In all his writings he took for his basis the maxim—there is no
security for France but in constitutional monarchy. His
style is energetic, and his arguments are expressed in warm
language; yet he never abandons the fundamental principle;
notwithstanding the strong measures adopted by the French
government to embarrass him, especially by the revocation of
the Edict of Nantes.
In 1837, during the short liberal ministry of M. de Mar-
tignac, M. de Salvardy was created Conseiller d'Etat, on
which occasion Charles X. said to him: "You must admit
the civic virtues of the Good Old Days." The constitution of
the Polignac cabinet was formed, in 1839, he resigned imme-
diately.
From 1830 to 1848, during the whole reign of Louis Phi-
lippe, M. de Salvardy continued to publish his separate
pamphlets, and his articles in the Journal des Debats. Am-
ongst these few have been more admired than his "Seize Mois;
ou la Revolution de 1830 et les Revolutionnaires." M.
de Salvardy became a deputy in 1833, when he observed the
same course of moderate and liberal policy as in his writings.
He was more than once called to fill some of the highest
ministerial offices of state, during the reign of the Citizen
King. He likewise became a member of the French academy,
and was created a count. After the coup d'etat, in Decem-
ber, 1851, he became a delegate of the United States, and
was deprived of office and banished from the country, in
1852, and admission to France was only restored to him
after his renunciation of American citizenship in 1856.
He died December 15, 1856, at the age of sixty-one.
SAN DIEGO. [Califomia, S. 2.]
SAN FRANCISCO, a city, port of entry, and the capital of
the State of California, United States of North America, is
situated on a narrow neck of land forming the southern
side of the entrance to San Francisco Bay, and be-
tween that bay and the Pacific Ocean, in 37° 47' N. lat.,
122° 26' W. long. The date of its foundation, which was only 156 in
1642, is the same as the Census of the United States in
1850; but in 1858 it was, according to the State Census,
34,776, of whom only 5245 were females. The govern-
ment of the city is vested in a mayor, recorder, aldermen, county
assessor, and treasurer.

The sudden rise of the present city of San Francisco, is
perhaps the most remarkable on record. But the place is
not devoid of interest in other respects, being one of the ear-
liest settlements of the old Spaniards for the charitable purposes
of converting the Indians to Christianity. Their fort, or strong-
held, called the Presidio, was fixed near the entrance of
the bay, on the southern shore, about half a mile inland. It
was a square inclosure, the sides of which were about 300 yards
in length, surrounded with ramparts and ditches, and a wall
of planks; wells lighted, and watched; and arrangements
were made for their sanitary supervision. Several of the
public buildings and churches are comparable with those in
Francisco, and surrounded by a number of houses and
places of amusement or dissipation, including not a few
game-houses of various grades. The manufactures of the
city are comparatively inconsiderable.

The commerce of San Francisco is very great.

The bay, which is 8 miles wide, affords excellent anchorage,
and is the natural outlet, not only for the almost unparalleled
mineral riches of California, but of a district the extreme
ferility of which has as yet hardly begun to be developed.
The city fronting the bay is few lined with wharves and
quays, and vessels of great burden can lie alongside to land
and take in their cargoes. Steamers are in regular and con-
stant communication with New York and the Atlantic ports,
and in consequence San Francisco has quickly passed be-
than San Juan de la Frontera, one of the provinces of
the Argentine Confederation, South America, extends
between 30° 30' and 32° 30' S. lat., 67° 30' and 70° 20' W. long.
It is bounded on the north by the Andes, on the west by the
province of La Plata, on the east by the Republic of Chili,

The zone lies to the north of Mendez, which it re-
sembles in general description. [Plata, La States of.] The surface of the country is described generally
under Plata, La. Extending along the eastern declivity of the
Andes, San Juan comprehends the northern part of the
Vale of Uspallata and a large portion of the plain which
separates the Pampa Hanga from the mountains of Cordova,
SAN

and contains the Lakes of Guanacoche. The Vale of Uspalata is barren and nearly uncultivated. The soil of the plain consists of sand, and is without grass, but covered with stunted prickly trees of the mimosa kind. It is quite barren, and produces no kind of grain or vegetables, except where it is watered. About the outlet of the Lluta River from the city of San Juan, there is some of its minor affluents. This irrigation renders the land exceedingly fertile; without any other manure, they produce most plentiful crops of wheat and maize. The ordinary crops of wheat are fifty for one, in height, and about four inches in diameter. About 6 leagues north of the city of San Juan, they have been two hundred and even two hundred and forty. The distance from a market and the difficulties attendant on the transport of heavy goods through the sand, greatly diminish the value of the land.

But as fruit trees, especially vines, succeed very well in this soil, wines and brandies are exported to a considerable amount. In the northern district, called Jacial, there are some gold-mines, whose produce is however not very great. Like the other provinces of the Argentine Confederation, San Juan is a federal state, owning little dependence on the central government. The executive power is vested in a governor, elected by the juntas, or provincial assembly.

San Juan, the capital of the province, is situated on the Rio de San Juan, in 31° 4' S. lat., 64° 57' W. long.: population about 7000. It contains the government house and other public buildings, and has considerable commerce, being the point of exit for the silver and brass imported from the province, and exported, and from which foreign goods are distributed to the interior. In 1833 the city was nearly destroyed by an inundation of the Rio de San Juan, by which three churches and several other public buildings, with numerous private houses were thrown down, and many of the inhabitants lost their lives.

SAN LUIS DE LA PUNTA, one of the provinces of the Argentine Confederation, South America, extends between 31° and 33° S. lat., 64° 3' to 67° 30' W. long. It is bounded on the north by Salta, on the west by Buenos Ayres, E. by Cordova, S. by the province of Buenos Ayres, E. by the provinces of Cordova, La Rioja, S.W. by San Juan, and S.E. by Mendos. The area is about 36,000 square miles. The population is about 25,000.

The country included within this province is described under Plata, as States of. It comprehends that immense tract of country which extends between the provinces of Mendoza on the west and Cordova on the east. Its north-western part runs northward to the border of the Great Salina, and it reaches southward to the country of the Ticanes Indians, but now claimed by the province of Buenos Ayres. No part of it possesses any considerable degree of fertility. The greatest number of the widely-scattered and miserable habitations are composed of montane estancias, or cattle-farms, occur along the road leading from Buenos Ayres to Mendoza, in the hilly country, where tracts of sandy land alternate with ridges of hills and sandy deserts over which the cattle may wander. As the grass is coarse and long, the pastures are indifferently cut; still cattle and sheep are abundant, and are exported to a small amount, together with some wool. The corn and maize which are raised are not sufficient for the consumption of the scanty and widely-scattered population. The country between the Sierra de Cordova on one side, and Mendoza and San Juan on the other, is still worse. As no fresh-water stream runs through it, it cannot be irrigated; and with the exception of a small number of springs, it is a complete desert. The climate is dry and hot; rain and snow are scarce, and the season is extremely dry. About 60 miles N. from the city of San Luis, have ceased to be worked; but the people of the village till the alluvial soil at certain places in the neighbourhood, and collect annually a small quantity of gold, in dust and small lumps (peplis). Like the other provinces of the Argentine Confederation, San Luis is a federal state; the executive power being vested in a governor elected by the juntas, or provincial assembly, but for many years there has been no really effective government.

San Luis de la Punta, the capital of the province, is pleasantly situated on the western slope of a hill, 3247 feet above the level of the sea, in 33° 17' S. lat., 65° 48' W. long. It is built on a情节-like elevation of sand-hills, and does not contain more than 1500 inhabitants. There is no other place in the province above the rank of a hamlet.

SAN PAULO, the capital of the province of San Paulo, Brazil, South America, is situated on one of the head streams of the river Tiete, in the plain of Pirassununga, at an elevation of 2464 feet above the level of the sea, in 23° 33' S. lat., 40° 45' W. long. The population is about 22,000, exclusive of the suburbs. San Paulo is one of the oldest towns in Brazil, having been founded by a colony of Portugees in 1560. It is the bishop, a spacious cathedral, 150 years old, and the college of the Jesuits, etc., etc. The only manufacturing is a government establishment for making fire-arms. Some coarse woolen cloths and hats are made. San Paulo is the general emporium of the commerce of the plain in which it is situated, and is the centre of its trade, containing all the manufactories of goods of Europe and North America are imported. Santos, the port of San Paulo, is 45 miles S.W. from the city; and the descent to it is so steep that nearly all the traffic is conducted on the backs of mules.

SAN QUENTIN. [California, S. 2.]

SAN SALVADOR, Republic of, Central America, extends along the Pacific Ocean from the Bay or Gulf of Conquaguanos, 20 miles south of the Bay, between lat. 15° 10' and 15° 30', to the town of Santa Ana, in 14° 50' and 14° 30' lat., and bounded E. by Nicaragua, N. by Honduras, W. by Guatemala, and S. by the Pacific Ocean. The area is about 8800 square miles. The population is about 38,000.

The city of San Francisco, cut, in proportion to its size, the most populous, of the republics of Central America. The surface is very unequal. The main portion of the coast extends along the Pacific in a generally west-north-west and east-south-east direction for about 140 miles; and on the west side of the city of Conchagua, and is extensive and safe, these harbours are, properly speaking, only open roadsteads, hardly accessible during the rainy season and the prevalence of the south-winds. As far northward as Libertad the shore is bordered by a narrow tract of low and generally level land from 10 to 15 miles wide; but farther north, up to Bouconost, the coast is more elevated and broken. The interior is very rugged, being broken by several short ranges of mountains of moderate height, but separated into distinct groups. About 15 to 18 miles south of the coast, is an old volcano, the active portion of it being 5000 feet high, and formed of volcanic stones, the most destructive; but Ysla is by far the most remarkable, from its unceasingly active condition, surpassing it in size, and in the imparlancy of its eruptions, any other volcano in America. Neither of the other volcanoes has exhibited a more active period of life, and have made no severely destructive eruption.

The rivers of San Salvador have only a short course, and are in their natural state of little importance; though it is asserted that they might easily be rendered of great service for irrigation, and some of them be made navigable for barges and other small craft. The chief river is the Lempa, which rising in Esquipulas, in Guatemala, forms a short distance the boundary between Honduras and San Salvador, receives the outflow from Lake Guija, whence crosses the eastern end of the Cordova province across the Rainbow mountains, and falls into the Conchagua at times being little to the westward of the Bay of Jiquilisco. It is a deep but rapid stream, and the bar at its mouth prevents vessels of even moderate burden from entering it. The other larger streams are the Rio de Paz, at the western extremity of the republic; the Jiboa, which falls between the Lempa and Port Libertad; and the Sirama, or San Miguel, all of which have their mouths obstructed by sand-bars. There are two lakes of some size in the state. The Lake of Guajuma, on the western bank of the Cordova province, is a circuit of about 80 miles, and is one of the principal feeders of the Rio Lempa. It is said to communicate with a subterranean channel with the much smaller Lake of Metapa. Lake Yopango, about 6 miles E. from the city of San Salvador, is a small tributary of the Jiboa. Mineral- and thermal-springs occur very numerously in various parts of the country.
Owing to the great inequality of surface, there is considerable variety of climate. As a whole, it is warmer than in Guatemala; but it generally regarded as healthy. The hotest and least healthy part is the low tract along the coast.

San Salvador has great agricultural capabilities. The soil is generally good; and in some parts remarkably rich, and the climate permits a considerable variety of crops to be profitably cultivated. The inhabitants are industrious races. Of their produce they export to the different parts of Central America. Nearly all the available land in the country is appropriated to individuals, and much attention has been paid to its cultivation, though now, from the long continuance of civil dissenion, agriculture is in a very neglected condition. Maize is cultivated to a considerable extent; wheat succeeds well only in a few places; several varieties of frioles, and most of the usual vegetables, are raised for the ordinary food of the people. Oranges, lemons, pineapples, plantains, and various fruits are extensively grown; sugar, cacao, coffee, tobacco, and cotton succeed very well, and might, were the country in a more settled state, be raised largely for exportation. Since the gold discoveries in California, a very large quantity of sugar has been grown in the northern part of the republic, and almost all the cacao, and most of the export tobacco is from this section. The coast west of Point Libertad is commonly known as the Balsam Coast, it being the only place where the article known as the Balsam of Peru is collected. This part of the coast is the most productive of the country, and the chief market for its products. There are large forests on the slopes of the mountains of the interior.

Cattle are numerous, and of a good breed; sheep do not so well; and hogs, on account of the great extent of swamps, are very scarce. There are but a few ducks and geese. An inferior kind of cheese is made in large quantities; butter is seldom made.

The mineral wealth of the state appears to be considerable, but it has been imperfectly developed. Gold has been obtained in several places. Some rich silver-mines were formerly worked, but, owing to the general insecurity of life and property, they have been for many years almost entirely neglected. Excellent iron-ore is obtained near Metapa, 15 miles south of Santa Ana.

The only manufactures are of the common articles of domestic consumption. They consist chiefly of coarse cotton goods, cutlery, and iron ware, and some of them used to be exported to the coast of Mexico. The trade of the republic with foreign countries is of comparatively little importance.

The exports in 1863 amounted in value to 700,000 dollars; the imports to 1,200,000 dollars.

San Salvador is divided into four departments, which are named after their respective capitals—San Salvador, San Vicente, San Miguel, and Santa Anna. In all, the republic contains 6 principal towns, 142 smaller towns, and 62 villages. The following are the more important places: the population being a loose approximation.

San Salvador, the capital of the republic, is situated on the Rio de Asisbata, a small affluent of the Lempa, in 13° 44' N. lat., 89° 5' W. long. The site of the city is more than 2000 feet above the level of the sea, on undulating ground, in a kind of valley, surrounded by high hills covered with wood, among which, in a north-eastern direction, and at a distance of about nine or ten miles, is the volcano of San Salvador, which at different periods has caused great devastation by its eruptions. The city itself was laid out with considerable regularity, and had in the centre a plaza surrounded by four squares, three sides of which were lined with shops, with porticoes before them, supported by a colonnade; while on the other side was the cathedral, an edifice which had no great claim to architectural beauty. The population of the city in 1861 was about 10,000. But from the night of the 16th of April, 1854, the city was entirely destroyed by an earthquake, and a very large number of the unfortunate inhabitants killed.

For several days previous to the sad catastrophe there had been slight tremblings of the earth, but as they caused no mischief, little heed was given to their premonition. On the evening of the night named however the shocks became more frequent and severe, and, being unattended with noise, the inhabitants became seriously alarmed, and many of them assembled in the great square. At length at 11 o'clock, a violent heaving motion of the earth occurred, which, in a few seconds levelled the cathedral, churches, university, and every other public building in the town. Whole blocks of warehouses were torn down; these were rendered uninhabitable; and the wells and fountains were either filled or dried up. Many of the inhabitants, as we have said, perished, and of the survivors many fled to other towns. The movements of the earth continued for several hours, and at length the government of the republic, in his address to the departments calling on them to assist the destitute citizens, intimated that measures were to be immediately taken for the selection of a better site on which to rebuild the city. Some manufacturers of iron, especially of cutlery and coarse cotton stuffs, were carried on in San Salvador; and some sugar and indigo for exportation. Sugar-plantations are numerous in the neighbourhood, as are also extensive orchards. Mannagos, or plums, oranges, lemons, and grapes, grow in the vicinity of the population. Near the city there are some warm and some cold rivulets, which afterwards converge, affording the inhabitants the advantage of having natural baths of every degree of temperature.

San Miguel, some distance east of the Rio Lempa, population about 7000, is noted for its fairs, of which the most important is held in November after the indigo crop.

San Vicente, on the right bank of the Lempa, contains about 5000 inhabitants. At the beginning of the year 1860, it has in its extensive plantations of indigo and sugar; in the mountains near the town are iron-mines, which were formerly profitably worked.

Sonsonate, near the western town and its suburbs. In the vicinity of the city, population about 8000, carries on as present considerable commerce by means of the port of Acayutla, exporting sugar to Peru and Chili, and rum, &c., to California. The Indians inhabiting the country about the town make very beautiful mate, which are also exported. In the neighborhood of Sonsonate is the Yalco, a very active volcano.

Other towns of less importance than those above mentioned are—Acaqucha, Apacatpeque, Cotzpeque, Metapa, Sacaatocalco, &c.

San Salvador is a republic with a legislative chamber of 25 deputies, but the government is really vested in the president.

The history of San Salvador is similar to that of the other republics of Central America. [Costa Rica, &c.; Guatamala, &c.; Honduras, &c.; Nicaragua, &c.]

The government of the republic of the United States of Central America, San Salvador became one of the federal states, and its capital was made the seat of the federal government; but the union was speedily dissolved, and San Salvador, like the other states, became an independent republic, and like them, its progress has hitherto been arrested by constant internal discord.

(Sources, History of Guatemala; Haeckens, Reise nach Guatemala; and Central America; Daily, Central America, &c.)

SANA is the capital town of the province of Yemen in Arabia, situated in 15° 8' N. lat., 45° 8' E. long. Sana, though the chief town of Yemen, is the seat of an independent chief, the Imam of Sana, who exercises authority over a wide district around, and is the representative of the Egyptian government, which has advanced its frontiers to Beit-el-Fakhil, a town in the Jemeah, about midway between Sana and the port of Mokha, on the Red Sea. Sana is pleasantly situated on an elevated table-land, surrounded on three sides by hill ranges, and its roads connect it with some of the most distant parts of the Egyptian government are so great, that it has been said, that the traffic may be turned to Aden, to which port Sana is as near as to Mokha. Coffee forms almost the only export; the imports are piece-goods, thread, and twist, Persian tobacco,
glass, silks, spices, and sugar. The town is walled, and indifferently fortificated. It lies about 65 miles in circumference, with the usual coats of arms, but with more regular streets, and the more opulent having windows of stained-glass. The

Imam has two handsome palaces, both built of hewn-stone and fortified, in the towns, and there are about twenty large gardens, with fountains and public fountains. Across the principal street a handsome bridge has been thrown, as in rainy seasons a torrent runs down the street, but occasionally the town is seven years without rain, and is much too dry in general to be healthy. The population was 602 in 1838; and of these three

7,587,000

6,358,972

The province of Sarawak, which extends between 1° and 8° N. lat., 100° 40' and 111° 40' E. long. It is watered by the river Sarawak and its tributaries. [Borneo.] The capital, Sarawak, formerly Kechin, contains a population of about 18,000.

SARCOCCOLI. [CHEMISTRY, S. 2.]

SARDINIAN STATES. The dominions of the House of Savoy constitute a monarchy, the head of which derives his title of king from the island of Sardinia. A general account of the island and of its capital will be found in the next chapter; to this we add the more recent information. These states consist of—

1. the duchy of Savoy; 2. the principality of Piedmont; 3. the duchy of Genoa; 4. the county of Nice; 5. the island of Sardinia. The latest information has been obtained from 19,775 square miles. The population in 1848 was 1,579,915.

The total area of the kingdom, including the island of Sardinia, is 20,075 square miles (about one-seventh of the area of France), and the total population in 1848 (the latest census) amounted to 4,918,084 (less than one-seventh of the population of France at the census of 1861). The continental territories are divided into 11 administrative divisions and 30 provinces; the area and population of which are given in the following table—

An account of these divisions and their chief towns is given under their respective heads. SARDOVIA, administered by a governor called Intendant, appointed by the king. The province is an aggregate of communes; each commune has a salsone, or mayor, who is subordinate to the intendant. For judicial purposes each commune has a justice called Tribunale, who sits in the chief towns. The provinces are divided into districts called Mandament, in each of which there is a justice of the peace, who has a secretary. There are in all 413 of these mandament. There are four supreme courts, which are also courts of cassation. The supreme council is the highest authority over all the provinces on the Italian side of the Alps and north of the Ligurian Apennines. The jurisdiction...
of the High Court of Genoa extends to all the provinces of the duchy of Genoa, with the exception of San Remo. The High Court of Nizza has jurisdiction over the provinces of Nizza, Oneglia, and San Remo. The High Court of Savoy, which sits at Chambéry, decides all suits within the limits of the duchy of Savoy, except those of a criminal nature, civil and the other for criminal matters. The judges are irremovable. There is an Admiralty Court which sits at Genoa; and tribunals of commerce are established in all the larger towns. The tribunals of commerce of Nizza, Genoa, Chambéry, Savona, San Remo, Genoa, Marseille, Tende, Toulon, and Nice are called Consolati. The towns and other communes have a communal council composed of notables of the place, at the head of which is the syndic. The council suspends the laws of the kingdom; and, in case of necessity, the commune, but its acts are subject to the sanction of the intendants of the province.

The government until lately was an absolute monarchy. The late king, Carlo Alberto, published a constitution for his subjects, dated February 8, 1849, which has since faithfully acted upon. It declares the Catholic religion to be the dominant religion, but gives perfect freedom of conscience to dissenters. The executive is vested in the king, who acts by decrees until Parliament meets; and it is his right to make proclamations or to make appointments to office, to sanction laws, also rest in the king. The legislative power is exercised by the king and two chambers—a Senate and Chamber of Deputies—which must be convoked every year by the king; and the Senate must be renewed in each chamber within four months. All financial laws must first be introduced into the second chamber. The freedom of the press and of the person is guaranteed. The judges are irremovable.

The army is recruited yearly by means of a conscription. Every conscript, unless he provides a substitute, is bound to serve eight years in the regular army, after which he is enrolled for eight years more in the provincial battalion of his respective district. In time of war, the provincial battalions are called into active service, and the army becomes thereby increased to about 150,000 men. The regular army in 1864 numbered 47,284 men and 7608 horses. The corps of carabiners, in number about 4000 (of whom 880 are in the island of Sardinia, which is free from the conscription), are charged with the police of the country, being scattered in detachments over the various provinces. In 1855 the army was increased in consequence of the king sending 18,000 men to aid the French and English against Russia in the Crimean war, 1857, 46,475.

The naval force consists of 4 sailing and 4 steam frigates, 4 corvettes, 3 higantines, 1 brig, 6 war steamers, and several smaller vessels, carrying in all 490 guns, and manned by 2860 men. The fleet is divided into three squadrons—those of Genoa, Villarfranca, and in the island of Sardinia. The mercantile navy numbered in 1857 2934 ships, carrying an aggregate of 197,924 tons, and 31,967 men, including captains, sailors, and workmen.

The public revenues of the state, as estimated in the budget of 1867, amounted to 138,957,321 francs; and the expenses to 147,326,686 francs. The national debt on the 1st of January 1861 amounted to 680,905,040 francs (27,528,300l.), including the loan guaranteed by the British government in 1858. The revenue is derived chiefly from land-tax, customs and excise duties, post-office, public works, &c.

The ecclesiastical administration of the central state is under the 4 archbishops of Turin, Chambery, Genoa, and Vercelli; 7 bishops; 16 vicars apostolic; 144 priests, 83 monks, 109 nuns, 80 deacons, 777 secular clergy, and 579 religious. The Sardinian Chambers in May 1865, all religious orders are suppressed, with the exception of those employed in "teaching, teaching, or tending the sick." The Vaincesans are the most numerous Protestant sect as yet in the Sardinian state. The Sardinians are particularly attached to the study of Geneva or Lausanne in Switzerland. They have churches in Genoa and Turin. Public instruction is afforded by the royal and communal colleges. In every province there are 1 or more royal colleges, in which grammar, rhetoric, and philosophy are taught; and in some of them there are chairs of law, medicine, and divinity. In most towns there is a communal college, besides grammar schools. Female education is afforded almost exclusively in the hands of nuns, of which there are forty-two in the kingdom. Scientific instruction is given in the two universities of Turin and Genoa, in which cities there are academies of sciences and of the fine arts. [Genoa; Turin.] There is a veterinary school at La Veneria near Turin, a school of telegraphic telegraphy at Turin. In 1848-50 a naval school at Genoa. Most communes have schools for boys.

The continental states of the king of Sardinia have several small carmine roads crossing the Alps, which intersect their territory. The most remarkable are:—1, the great road of Mont Cenis, leading from Chambery to Turin, constructed by Napoleon; 2, that of the Simplon, leading into Switzerland, likewise constructed under Napoleon; 3, the road from Genoa to Sarrans and Lecons along the Eastern Riviera; 4, the road from Genoa to Novi by Serravalle; 5, the road Della Cornice, from Genoa to Nizza, along the Western Riviera, begun under Napoleon, and finished under the king; 6, the road from Chambéry, which, under Louis XVI., was projected to form a connecting road between Montmellian and the Simplon; 7, the road from Turin to Genoa through Alessandria; from Turin to Cuneo, to Pignerolo, and to Susa; from Alessandria a line runs up to Novara. Along these roads electro-telegraphic wires are laid down and the city of Turin has electric communication across it. The construction of the Simplon line of Spexetia with the island of Sardinia, from the south-western point of which it has been proposed to carry electro-telegraphic cables to Bonis in French Africa. A railway is projected from Annecy, by chambery, to chambery, to Montmellian, and on the istre, up the left bank of the river to the confluence of the Arc, and up the valley of the Arc to Modane. This line in all probability will be extended from Annecy to Geneva, from Montmelian to Grenoble, so as to form a junction with the French railway system; and the project is to cut through the Alps under Mont Cenis, so as to unite the Savoy railroad at Modane with an extension of the Turin-Susa line to Grande-Croix, which has been long entertained with great favour by the people and government of the Sardinian state.

The plains of Piedmont are well supplied with canals, chiefly for the purpose of irrigation, the principal of which are in the provinces of Alessandria, Vercelli, Biella, Casale, Ivrea, Alba, and Turin. The river system of Piedmont is described under Po.

The staple products of the continental Sardinian territories for exportation are—silver, rice, hemp, wine, and oil. Most of the wine is consumed in the country. The principal manufactures consist of paper, silk, woollens, laces, glass, and cotton-yarn. The importation of colonial articles and foreign manufactures takes place chiefly through the port of Genoa. A considerable trade is carried on with Switzerland and Germany by the Lago Maggiore, and the Bernardino road leading to the Grisons.

The Sardinian States have Switzerland on the north, France on the west, the Mediterranean on the south, Austrian Italy, Parma, and Tuscany on the east. They comprise the provinces of Ivrea, Casale, Biella, Alba, Turin, and the Ticino. The Sardinian portion of the Lucania lies east of the Magna. The surface is covered on the west and north by the Alps, on the south by the Apennines, and between these two great mountain systems lies the most extensive and valuable of the valleys and plains that form the basin of the Po to the junction of the Ticino. The face of the country is described in the articles Alps, AYENHUS, GENOA, PIEMONTE, SAVOY, under the names of the several administrative divisions or provinces.

SATURNIA. [FOGOLARI, S. R.] SASIN. [ANTIOPE.] SATURNIA, a genus of Insects belonging to the order Lepidoptera, and family Bombycidae. The antennae are fringed in the male; the head is small; the wings are very broad and entire; the palpi and trunk are wanting.

S. Pavo, minci, the Emperor Moth, is one of the hand-
somest of the British species of Moths. It is about 3 inches wide. The colour is grayish-brown, faintly tinged with purple; the hinder margin of all the wings has a band of pale brown and purple, the hinder band being much waved. The centre of each wing has a large spot or occelus, which is placed on a light ground; it consists of a black pupil, with a yellow or gray iris, and partly surrounded by a light blue crescent. The lower band of the greenish wing, having a black band on each segment adorned with pink tubercles, bearing a whorl of six hairs diverging like a star. It constructs a curious cocoon, the extremity not being closed, but terminated by a converging circle of very stiff hairs, which enables the insect to make its escape from within, but completely prevents all ingress.

To the genus *Sternura* some of the largest of the *Lepidoptera* belong. *S. Atlas*, the Giant Atlas Moth, has wings measuring 7 and 8 inches across. This species also, with *S. Cerealis* and *S. Lysia*, have their wings produced into a tail. The cocoons of *S. Cyntha* and *S. Mykilla* are used in India for the production of silk. Latrielle states that these are the wild species of silk-worm of China. *S. Cyntha* is the Arrindi Silk-worm of India. (Boxburgh, 'Linn. Trans.,' vol. vii.) *S. Promethea*, a North American species, forms its cocoon within the leaf of a saussafra-tree, having previously fastened the stalk of the leaf to the stem by a strong silken web, whereby it is prevented from falling with the other leaves. (Weswood.)

SAURINS. The following is a synopsis of the families of the *Sauria*, adopted by Dr. J. E. Gray in his 'Catalogue of the Specimens of Lizards in the British Museum.' The generic and specific names of *Lacertididea* are given, the other large families are described under their proper names —

Order I. Lizards. *Sauria.*

Mouth not dilatable, jaws toothed, the lower jaw-bones being united by a bony nut in front. Eye generally with distinct eyelids; drum of the ear generally distinct. Limbs four, distinct, rarely in such a rudimentary state as to be hidden under the skin. Toes clawed. Body elongate, rounded, covered with imbricated or granular scales; ribs distinct, mobile, and with a distinct sternum. Tail elongate, tapering, rarely prehensile, generally covered with whorls of scales. Eggs with hard skin. The young not undergoing any metamorphosis.

Sub-Order I. *Leioptosauria.*

Tongue flat, elongate, and bifid.

Tribe I. *Cyclosaura.*

Scales of the belly square, in cross bands, of the back and tail rhombic and imbricate, or circular and subgranular. Tongue elongate, flattened, free, nicked, or with two elongate cylindrical horn-like tips. Eyes diurnal, with two valvar lida. Feet for walking, with unequal toes.

a. Head with small many-sided shields. Tongue sheathed at the base.

1. *Monotraca.*—Head-shields flatish, scales small. Inhabit the Old World and Australia. [Mohora.]

2. *Heloderma.*—Head-shields and scales of body convex, tubercular. Teeth with a groove behind. Inhabit the New World.

b. Head with large regular shields. Tongue mostly free at the base.

* Sides flatish, covered with small often granular scales.

4. *Lacertinae.*—Head pyramidal, covered with regular many-sided shields; super-orbital plate rigid. Throat scaly, often with a fold of hair, and of colour; neck, dorsal, and anal, of the same. Tongue elongate, flat, free at the base, erectile, long-foled. Teeth hollow, rounded. Scales granular or rhombic, keeled. Sides flat, covered with small granular scales. The species inhabit the Old or Eastern world and Australasia.

Synopsis of the Genera.

1. *Nostotel.* erect, in the lower hinder angle of the nasal shield, just above the labial shield, with one or two shields behind it. Eyelid distinct.

a. Toes simple, compressed, not keeled nor fringed. Collar distinct.

b. Scales granular or 6-sided, elongate. Posterior nasal shield single. Collar distinct.

Zoetes.—Lower eyelid scale, opaque.

Z. ocyphala. — Long-Headed Lizard, a species brought by Mr. Smith from Spain or Madeira.

Z. Taurica, a native of the Crimean, Morocco, and Sicily.

Z. leovia, the Striped Lizard, a native of South Africa.

Z. Berbiana, a native of Australasia.

Z. Galotti, Madeira.

5. Scales granular or 6-sided, elongate. Posterior nasal shields 2, small, one above the other. Collar distinct.

Lacerta.—Lower eyelid opaque. Chin-fold distinct. Abdominal shields narrowed behind.

L. viridis. — The Great Britain Lizard. It is the *L. stirpiaea* of Miller-Edwards and others. The upper hinder nasal small, rather in front of the larger lower one; scales of the temple small, unequal, irregularly many-sided, often with a larger central one; throat fold indistinct, brown, spotted or yellow with black; sides green, brown-eyelid, beneath white. This species is a native of Great Britain, and is especially abundant in the neighbourhood of Poole in Dorsetshire. Its general abode is on sandy heaths, where, from the rapidity of its movements, it is often taken for some form of snake. On account of the rapid locomotion it is not often caught. It does not bear confinement, but pines away and dies. When caught it often bites, but no ill-consequences are the result.

The female lays her eggs to the number of 12 or 14 in hollows in the sand, which she excavates for the purpose. They are subsequently hatched by the heat of the sun. The eggs appear to be laid a considerable time before they are hatched. In this respect this species differs very much from the common lizard, which always brings forth her young alive. This lizard is larger than the *Zoetes niger*, as those of average size measure about 7 inches in length.

L. viridis, the Green Lizard, has the scales of the temple inequilateral, many-sided, with a central larger one; back granular, oblong, with shelving sides; throat-fold distinct. This species is a native of Guernsey and Jersey, and also of the south of Europe. It is much more readily caught than the last species, and never attempts to bite. It may be readily tamed and taught to come to the hand for food. It will lie coiled in the two hands, and never attempt to escape.

L. ocellata and *L. lervia*, both natives of the south of Europe, are the only other species of the typical genus *Lacerta*.

Thruss.—Lower eyelid transparent. The only species is *T. persepolitana*, a native of Algiers.

Terra.—Lower eyelid opaque. Chin-fold distinct. Abdominal folds and shields square. *T. punctata*, a native of Madeira, in Portugal, is a species.

Nucora.—Lower eyelid opaque. Chin-fold indistinct. Abdominal shield narrow behind. Preanal shields one below the other.

N. Landonii, a native of the Cape of Good Hope.

N. tanalata, a native of South Africa.
2. Plate of eyelids of toes.

N. exiguus and N. chalybeus, the Small Lizard and Steel-Black Lizard, are natives of the Canaceus.

c. Scales rhombic, keeled. Posterior nasal shields, small, one above the other.

*Notopholis.*—Collar and throat-fold distinct.

N. fitzingeri is a native of Sardinia.

N. Copena is a native of South Africa.

N. melanosoma inhabits the Morea.

N. nigropunctata, a native of the island of Corfu.

*Tropidosaurus.*—Collar and throat-fold distinct.

T. montana, a native of Java, is the only species.

*Algira.*—Ventral shields roundish, thin.

A. barbiora, the Zermoromet, is a native of Algiers.

A. Capensis and A. Dumoralis are natives of the South of Africa.

*Acantholacustris.*—Toes fringed on the sides.

A. Bidii. Found in Algiers.

A. Copena. South Africa.

A. Scorign. Algiers.

A. Lison-maculatus. Morocco.

A. inornata. Tripoli.

*Psammodromus.*—Toes not fringed on the sides. Collar indistinct.

P. Hispanius, the Garrines, is a native of Spain.

P. cinereus inhabits the South of France.

11. Nostril horizontal on the ridge, between three swollen scales, one between the nostril and labial. Toes keeled beneath or fringed on the side.

a. Eyelid distinct.

*Scapiterna.*—Toes depressed, fringed on the edge, not keeled beneath. Collar indistinct. S. granimina, a native of Nubia, is the only species.

*Erenga.*—Toes compressed, keeled beneath, not toothed on the edge. Collar distinct. Preanal shields small, in several series, in central series one behind the other.

E. arguta. The Arguta is a native of Tartary.

E. velox. The Crimean.

E. Kosnii. South Africa.

E. Copena; E. Burchelli; E. Forsellia; E. Namanganis; E. Inquabria, are also described by Dr. Smith as natives of South Africa.

E. lineo-ocellata. South Africa.

E. pulchella. South Africa.

*Mesita.*—Toes compressed, keeled beneath, not toothed on the edge. Collar distinct. Preanal shield single, semicircular, with 1 or 2 arched series of smaller ones round it.

Cubrita. Toes rather compressed, keeled beneath, not fringed on the sides. Collar none.

C. Lecheeanaulii, a native of India, is the only species.

b. Eyelid rudimentary. Eye circular, exposed.

*Ophiotes.*

O. elegans is found on the shores of the Mediterranean.

O. macobractaeus is a native of Asia Minor.

** Sides with a distinct longitudinal fold, covered with small granular scales.

5. Zonuridae.—Ears distinct. Limbs distinct, or rarely quite hidden.

6. Chalididae.—Ears hidden under the skin. Limbs very short; femoral pores none. Lateral fold indistinct. [Chalididae.]

*** Sides rounded, covered with scales like those on the back.

8. Chirolekidae.—Scales of the back imbricate, 6-sided, lanceolate, keeled, narrow, in cross series; of the tail in rings, alternating with each other. Ears hidden. Femoral pores distinct.

10. Chlorosariaeidae.—Scales imbricate, all elongate, rhombic, keeled in longitudinal series, the keels forming longitudinal ridges. Limbs simple, undivided. Temples scaly.

Tribe II. Griesauridae.

Scales of the belly and (almost always) of the back and sides quinquecennial, roundish, imbricate. Sides rounded. Tongue narrow, short, flat, and slightly nicked. Head with regular shields.

a. Eyes distinct, exposed, eyelid rudimentary. Head conical.

b. Eyes distinct, eyelids distinct, connivent. Head conical.

15. Scinisidae.—Rostral shield moderate, triangular. Nostrils in a plate between the frontal and labial shields.

17. Acotidae.—Rostral large, cup-like. Nostrils in the rostral, with a narrow slit to its hinder edge.

c. Eyes hidden under the skin.

18. Typhlimoridae. —Head conical. Rostral shield cup-like. Nostrils in the rostral shield, with a slit to its hinder edge.

Sub-Order II. Psychoglossa.

Tongue thick, convex, attached to the gullet at the base.

Tribe III. Nyctiura.

Scales of the belly small, rhombic, imbricate; of the back and sides granular. Tongue thick, short, convex, end slightly nicked. Eyes nocturnal; eyelids circular, not constrict; pupil linear, erect. Feet for walking; toes unequal, scaly beneath, and generally dilated.

Tribe IV. Sirobiloauru.

Scales of the belly small, rhombic, imbricate; of the back and sides imbricate. Tongue thick, short, convex, end slightly nicked. Eyes diurnal, with valvar eyelids; pupil round. Feet for walking; toes unequal. 21. Geckoida. —Teeth on the inner side of the jaw-bone. New World. [Swan.]

23. Agamidae.—Teeth on the edge of the jaw-bones. Old World and Australasia. [Dagonina, 2.2.]

Tribe V. Dendronauru.

Scales of the belly, sides, and back, granular. Tongue elongate, subcylindrical, worm-like, very extensile. Eyes globular, very mobile, with a small, central, round opening. Toes equal, united into two opposing groups.

24. Chameleoniidae.—Teeth on the edge of the jaw-bone. Old World. [Chameleons.]

SAUSSUREA, a genus of Composite Plants belonging to the sub-order Cynaroploclaeae. The florets are all herma-
phodite and tubular; the authors with oillated sets at the base; the involucres is imbricated and unarmed, the receptacles a few foam the upper of the genus consisting of short rough bristles, the inner one feathery.

*S. alpina* has a stem from 3 to 19 inches high, erect, downy, and simple, terminating in a small corymb of heads with pinkish florets and purple anthers; the leaves are lanceolate, with sharp points, and an inner involucel lanceolate, the upper ones sessil-ealy, all distantly toothed, the heads in a dense corymbe, the involucres subcylindrical, with depressed hairy scales. This is the only British species in the genus that is common in upland situations.

(From the *Manual of British Botany.*

**SAXIFRAGE. [SAXIFRAGA.]
SAXIFRAGE, GOLDEN. [CHRYSOPHYLLUM, S. L.]
SCARLATINA RHEUMATICÆ. [Phlegm, Practice of, unsettled.]**

**SCHADOW, JOHANN GOTTFRIED,** an eminent German sculptor, was born at Berlin in 1764. Passionately found of art when a boy, he was yet unable, owing to the poverty of his father, to obtain any instruction until a sculptor kindly offered to teach him. He soon mastered the rudiments of art, and eventually determined to devote himself to his teacher's profession. But having formed an attachment to a young lady, he fled with her to twenty-first century. There he produced his first work, of which the commencement of his fortune; for his father-in-law not only forgave the young couple, but furnished funds wherewith Schadow might proceed to Italy to continue his education. He remained in Rome from 1768 to 1788, chiefly occupied in the study of art. He then returned to Berlin and soon found ample patronage. The first important work executed by him after his return was the monument to Con von der Mark, natural son of Frederick William II, erected in 1789 in the church of St. Dorothy at Berlin. Among other great works with which his chisel has adorned Germany are the colossal statue of General Zieten in hussar's uniform; the equestrian statue of Frederick the Great at Göttingen; a life-size marble group of Queen Louise of Prussia, and the statue of the Duchessa di Cumberland; a statue of Duke Ludolph of Dessau for the Lustgarten at Berlin; an equestrian statue of Field-Marshall Blücher at Ros托ck; the monumental statue of Tatenstein at Breslau; that of Luther at Wittenberg; the quadripla on the Brandenburg Gate; and the sculpture on the Mint at Berlin: he also executed a considerable number of portrait busts of the most eminent contemporaries.

For many years before his death Schadow was regarded as the patriarch of the modern school of sculptors in Germany, as an evidence of the honor in which he was held, it deserves to be mentioned, that whilst the old man still lived, the street in which he dwelt in Berlin was called by his name. This is the way of the countrymen to break through the classic conventionalism of his predecessors, and, without departing from the sober dignity of sculpture in style, to add a more forcible expression of character, and a stricter adherence to the actual model in attitude as well as in drapery. His great excellence lay in portrait, and he had ample opportunities of putting forth his powers. Appointed professor in the Academy of the Fine Arts at Berlin some time prior to the close of the 18th century, he from 1822 to his death held the office of director of that institution, and among those who were successively his pupils are a large proportion of the best sculptors of Germany, including Rauch, Dennecker, Tieck, Zanner, &c., in most of whose works evident signs of his influence may be traced. Schadow continued from time to time to develop portions of his dёtrines in public addresses or in detached essays; but on the whole there was in those no important alteration of his philosophy as already given forth in the first fifteen or so of the present century. Meanwhile, as he had burst away from Fichte, so his old friend and associate Hegel had burst away from him. The germs of a difference between Hegel's philosophical teaching and that of Schelling continued to develop and finally to come out into the open as early as 1806. If not earlier; they had been developing in subsequent works of Hegel; and at length, in 1817—when Hegel was appointed to the Philosophy chair at Berlin, which had been vacant since Fichte's death—Hegelanism continued to develop different from Schellingism, as had dispossessed the system of Fichte. The struggle between Hegelianism and the natural Gestaltung of the Menschlichen Kopfes in Umrisse bildlich dargestellit! ("National Physiognomy, or Observations on the Differences of the Various Species of the Form of Human Heads, represented in Typical Outlines").

**SCHELLING, FRIEDRICH WILHELM JOSEPH,** one of the chief names of modern German philosophy, of which Kant, Jacobi, Herbart, Fichte, and Hegel are the other chiefs, was born at Leonberg in Württemberg, in 1775. He studied first at Tübingen, where he had Hegel for his college-fellow, and where the two future rivals in philosophy formed the friendship which was to last to the end of the younger man, was somewhat the older philosopher, and Hegel was first indoctrinated by him in philosophy. From Tübingen, Schelling went to Leipzig and Jena—his attraction to Jena being Fichte's philosophical lectures. He started as a materialist, but later became a religious critic and disciple of Fichte; and it was not till 1798—when, on Fichte's removal from Jena, Schelling succeeded him in the Philosophy chair of that university—that Schelling became aware of his own differences from Fichte's system. He had already been a contributor to Fichte's Jena Journal; but now, in preparing his own course of lectures, he necessarily enlarged his speculations. In 1798 he published *Erster Entwurf eines Systems der Naturphilosophie, zum Deutlichen und Erkennenden der Natur.* Some of his lectures themselves that he first effectively disseminated his new philosophical ideas. Hegel, who had in the mean time been living at Frankfurt-on-the-Main and elsewhere, now, among others, on the death of Schelling's first wife, was advocated in common by himself and Hegel—the two acting as joint editors of a journal, and Hegel appearing independently, in Schelling's interest, as the author of an essay on the *Difference of the Systems of Schelling and Fichte.* 

In 1802 Schelling fled from Jena for Berlin, where he lived, as he had succeeded Fichte; and in 1807 he removed from Würzburg to Munich, where he remained till 1841. By the year 1814, when Fichte died at Berlin, the philosophy of Schelling, who had then been seven years settled at Munich, may be considered as having gained the ascendancy throughout Germany, as a development beyond that of Fichte and superseding Fichte's system. This had been owing partly to the diffusion of Schelling's views by himself personally in the lecture-room at Jena, at Würzburg, and at Munich; but partly also to various scattered writings—some in the form of contributions to journals, some as reprints of the substance of his lectures, some as public addresses, and some as dissertation papers—each of which, regarded as a whole, was not without its influence on the thought of the time. Among the most important of these publications were the following:—"On the System of Transcendental Idealism," 1800; a discourse entitled "Bruno, the First of the Philosopher of the Doge," 1802; an essay entitled "Ideen in einer philosophischen Natur, als Einleitung in das Studium dieser Wissenschaft," 1813; "Darlegung des wahren Verhältnisses der Natur-Philosophie zu der vernichteten Fichtschen Lehre," 1806; a discourse, "Über das Verhältniss der bildenden und der menschlichen Kunst zu der Natur," delivered before the Royal Academy of Sciences in 1807; a work entitled *Von der Weltseele, eine Hypothese der höheren Physik zur Erklärung allgemeinen Organismus, nebst einer Abhandlung über das Verhältniss des Realen und Idealen in der Natur,* 1809; the first volume of a collection of his *Philosophische Schriften,* published in the same year; and a series of fourteen lectures, "Über die Verhältnisse der philosophischen Vernunft im System der Natur," published in 1813.

By the time of his death, Schelling had lived through the republication and the republication of his *Determinate in public addresses or in detached essays; but on the whole there was in those no important alteration of his philosophy as already given forth in the first fifteen or so of the present century. Meanwhile, as he had burst away from Fichte, so his old friend and associate Hegel had burst away from him. The germs of a difference between Hegel's philosophical teaching and that of Schelling continued to develop and finally to come out into the open as early as 1806. If not earlier; they had been developing in subsequent works of Hegel; and at length, in 1817—when Hegel was appointed to the Philosophy chair at Berlin, which had been vacant since Fichte's death—Hegelism continued to develop different from Schellingism, as had dispossessed the system of Fichte. The struggle between Hegelianism..."
According to Schelling, a knowledge of the absolute is the only true philosophy, and such knowledge is possible. But it is possible only to him who has attained a certain kind of understanding—by what he calls "Intellektual Intuition," which is a kind of falling back or swooning of human reason into the absolute as being identical with itself. If one can know the absolute, it can only be because man himself is identical with that absolute in the same thing as existence, because thinking and being are one. But this is but one aspect of the doctrine of the identity of thought and being, of the subjective and the metaphysical absolute. The words come to cognize only through identification with it, and which we may designate to be regarded in its original condition as neither object nor subject, neither nature nor mind, but as the union, the indissolubility, the immutability of both. It has become all in all, and the subject, which originally but insidiously is now continually justifying itself higher and higher, from the lowest manifestations of what is called matter, up to organic existence and the activity of reason itself in the guise of humanity. In this movement of Deity or the Absolute One, which constitutes the Life of the Universe, there are two modes—first, the expansive movement, or objectifying tendency, by which the absolute reaches forth, so to speak, into actual existence, and out of the natura naturata there arises the self-subsistent and creative natura naturans; and, secondly, the contractive movement, or subjectivising tendency, by which the natura naturans falls back on the natura naturata, and becomes conscious of itself. The foundation of the absolute as engaged in the first movement—that is to say, in activity more than in passivity—is, naturally, natural philosophy; and only when the philosophy of nature is so considered—that is, when nature is considered as so many successive potentiations of the absolute in the form of experience, can it be truly studied. A perfect intellectualising of the laws of nature into laws of intuition and of thinking would be the highest perfecting of the science of nature." Of this style of treating the laws of nature, as modes by which the absolute proceeds in the development of its own activity, there exists, Schelling himself set the example. He interpreted what is called inorganic nature, with its laws of gravity, light, magnetism, and electricity, as being the absolute in what he called its "first potencies," or working on in its first efforts for converting the possible into the actual. Even here the subjective and the objective were already differentiated, but objectivity predominated. Then came the second potencies, or potencies of chemism, representing a higher phase of the same activity. Here nature, with this succeeds the third potencies, of organically living nature, where we first see the aspect of consciousness or predominating subjectivity. Though Deity is immanent in all nature, it is in man the Deity becomes consciousness; and the highest phase of the third potencies, of man, is its identification with the infinite, and relapsing into the infinite. The ideal in man also corresponds to the real in nature; and in the perception of this is the true philosophy of art.

Schelling was the doctrine of 'absolute identity,' as it was propounded in Schelling's first or earlier philosophy. For a fuller view of the immense extention which he gave to it as affecting every possible department of thought, we must refer to his own writings; or to a very accurate and profound summary of Schelling's system given by Chalmers in his 'Historical Development of Speculative Philosophy from Kant to Hegel' (of which there are two English translations); or (for more popular purposes) to Mr. Morell's 'History of Speculative Philosophy,' vol. ii. pp. 161 to 165. There is a French work entitled 'Schelling; Esprit Philosophiques, et Moraux propre a donner une idee generale de son Systeme: traduit de l'Allemand par F. Bénard,' 1844. This work includes Schelling's lectures on the methods of academic study. His discoveries on the philosophy of art is accessible in English. (Chapman's 'Catholic Series,' 1844.)

Apart altogether from the scientific comprehensive philosophy which Schelling aimed, there was much in the spirit and phrasing of his system—in such phrases, for example, as 'the rhythm of the Universe,' the 'cosmic indistinctness of the external,' the 'immanence of Deity in Nature'—to captivate and fascinate. Schelling was a species of sublime Pantheism, accorded well with the tone of German thought as affected or determined
by Goethe, Tieck, and other poets. But, as we have said, the system did not meet with entire satisfaction even in Germany. On the other hand, Hegel had tried to tear it to pieces on the score of its substitution of enthusiasm and poetry for logic, and had promulgated a system which found more acceptance with harder minds; on the other, the re-awakened Christian sensibility, and the exigencies of the French Pantheon, leaving no room for that 'personal God' which the human soul demanded as essential to true religion, and, moreover, in its identification of man with deity, contradicting those notions of sin, redemption, and the like, which finds its home in the experience of humanity. Working his way against these attacks, or, at least, to re-issue his system in a form which would save it from attacks from the latter quarter, was Schelling's object during the last portion of his life. This object, later lying as it now does in an at least ascertainable, will be found in Chalybeus. Suffice it here to say that, by a peculiar modification of his theory of the absolute,—according to which modification he now manifested that, though nature and Deity were identical, yet nature might not he and was not co-extensive with all Deity, that is, that the absolute might be considered as being in all objects and yet as not being exhausted in all objects taken collectively, but as being moreover a certain force or fund of unobjectifiable will and reason,—Schelling imagined that man, the noblest of all creatures, combined within one body all the most peculiar part of Deity, and that 'what is immanent in nature is that in God which is least God himself,' he arrived at the doctrine of a 'personal God,' and also at the notion of 'human imperfection,' and moral evil, and so he reconciled his philosophy with the Christian, and sanctified the world's history as a fall from good and a divine recovery.

ScHirRHUS. [Phys, Praelections On, under Microscopic Diagnosis, &c.]

1837. An Argillaceous Rock, of a coarse laminated structure. [Slaty.]

Schnee Von KarolSfeld, Julius, was born at Leipzig on the 26th of March, 1794. His father, Hans Schnee von KarolSfeld (born 1784, died 1840), a painter of some celebrity in his day, was director of the Art-Academy at Leipzig, and Julius received his earliest instruction in art from him, though he was desirous that his son should adopt a different profession. But the boy displayed at an unusually early age such remarkable talent for art, and so earnest a desire to follow it, that the elder Schnee, by his own voluntary act, and at the age of sixteen Julius was entered a student in the Academy of Painting, at Vienna. There he distinguished himself, though the formal conventionalisms indulged in by most of the pupils of the Academy in Vienna, was of the greatest assistance in the development of his original genius. Happily in good time he proceeded to Rome (1815) where he at once attached himself to the society formed under the auspices of Cornelius and Overbeck, and when that remarkable cluster of young German painters brought their productions fairly before the artistic world, Julius Schnee was recognised as one of the most accomplished of the promulgating band. His work the 'Wedding in Cana,' attracted so much notice that he was chosen along with Cornelius and Overbeck to paint the walls of the villa Massimi at Rome, in the revived art of fresco, with designs from the trio of great Italian poets, Dante, Ariosto, and Tasso. To Schnorr was assigned Ariosto, and his designs were received with general approbation. He also produced works which were particularly admired and of which, if 'Ruth in the field of Boaz,' 'Flight into Egypt,' and other important works.

At Rome Schnorr had gained the friendship of Niebuhr, Humboldt, and Döll, by whom he was introduced to the monastic patronage of France, and to the two last-named crowned princes and afterwards kings of Bavaria. When Ludwig set about the construction of his magnificent works at Munich, Julius Schnorr was one of the artists he summoned to assist in decorating them. The paintings of Schnorr, both in the older and in the new buildings, were suspended in order to complete the decoration of that portion of the palace called the Fest-Saal, and great

SCHolS Feld, REV. JAMES, M.A. was born November 13, 1819, at Olden, Yorkshire, England. His father, Daniel Scholesfield, was minister of the Independent Dissenters' chapel, in that town. He was educated in the school of Christ's Hospital, London, became a Grecian there, and obtained several prizes. He was entered of Trinity College, Cambridge, and graduated B.A. in 1842, and M.A. in 1819, in that year obtained the Craven University Scholarship. He took holy orders in 1813, by special permission, before he had taken his degree of B.A. Soon afterwards, on proceeding to his degree, he attained the place of Senior Chancellor of the University of Cambridge of the Order of the Garter. He was then curate to Mr. Simeon, of Trinity Church, Cambridge. In October 1815,
He was a Fellow of Trinity College. Having taken his degree of M.A., he obtained in July 1823, by presentation of his college, the perpetual curacy of St. Michael's, Cambridge, where for thirty years he performed the duties of his sacred office with unwearying zeal and assiduity. On the death of Mr. Dobson, in October 22, 1852, Mr. Scholz was Regius Professor of Greek in the University of Cambridge. In 1827 he married, and in the same year he commenced the courses of lectures on the principal Greek authors, which, with no interruptions, he continued for a quarter of a century. In the latter part of his life he published a work on Ἀθηναῖον, Plato, Aristophanes, Thucydides, Sophocles, Demosthenes, and Pindar, returning to each, on an average, once in seven years. In 1844 he made a tour in Scotland, and there raised their applause by his learned and instructive discourses. On the 11th of November 1849 the church of St. Michael was burnt down. On the following day Dr. French, canon of Ely, died, and Mr. Scholz succeeded him in the canonry, the prebend being attached to the Regius Professorship of Greek. St. Michael's church was rebuilt, and was re-opened January 11, 1852. Professor Scholz's health, however, had been failing for some time, and he was ordered by his medical adviser to refrain from preaching, and take rest in some quiet and pleasant place. For this purpose he retired to Hastings, where he died, April 4, 1853. He was buried at Fairlight, near Hastings.

Professor Scholz's principal literary publications are as follows: In 1826 he published a new edition of Pearson's Eucharistia Mystica. In 1827 appeared his Pompeia Longiton. "Treatise on the Greek Article," an edition of Ἀθηναῖον, with notes critical and explanatory; and a new edition of Bishop Leighton's "Proleseia." His next work was 'Petri Pauli Dobree Adversaria,' containing Dobree's notes on the Greek Books of the New Testament and minor orators, of which Part I. was published January 1831; Part II. November 1831; and Part III. January 1833. In 1832 he published 'Hints for an Improved Translation of the New Testament,' and a "Commentary on the New Testament," in which the original Greek and authorised English versions stand side by side. In 1833 was published an edition of the "Eumenides" of Aeschylus. Several of his sermons have been published in a separate form.

(Memorials of the Rev. John Scholz, M.A., late of Trinity College, Regius Professor of Greek in the University of Cambridge, Perpetual Curate of St. Michael's, and Canon of Ely, by his Widow, with Notes by A Literary Character by the Rev. William Selwyn, M.A., Canon of Ely, 1850, 1851.)

SCHOLZ, JOHANN MATTHIAS AUGUST, was born at Karlstadt near Breslau in Prussian Silesia on February 8, 1794. He received his early education in the Roman Catholic gymnasium of his native town, and in Leipzic, where he studied theology and philology, and in 1814 gained a prize in the Roman Catholic theological faculty for his essay on the Parable of the Vineyard. Shortly afterwards he commenced his critical labours on the text of the New Testament, and with this object after he had for two years availed himself of the materials in the library of Vienna, in 1817-19 he visited Paris and London, Switzerland and Italy. In 1820, immediately after being appointed professor extraordinary of theology at Bonn, he joined the expedition under Minniel for the exploration of Egypt and the neighbouring countries. The travellers disagreed and parted, but Scholz journeyed through Egypt, Palestine, and Syria for four months, when he returned to Trieste. At Breslau in 1821 he took priest's orders, and in 1825 he was appointed professor of theology in the university and a canon of the cathedral. He died in November 1852. Among his principal works we may mention 'Reise in die Gegend zwischen Alexandrien und Ptolemais,' which was a selection from his diary, and was published in 1829. In 1826 he issued at Bonn his 'Communia de Gogalathae et Jesu Christi Sepulcri Situ,' in 1834 his 'Handbuch der biblischen Archäologie,' in which he collected the various theories which have been put forward on the subject, the text of the New Testament, under the title of 'Novum Testamentum Graecum,' in two volumes. Scholz's scholarship as a philologist has been generally acknowledged, and his labors are held in high estimation.

SCHOOLS.—Under the head of Schools in vol. xxx, page 50, we remarked the increased interest which was then taken in the subject of the education of children especially those of the poorer classes. From that time the interest has greatly increased; many plans have been proposed, some have been adopted, and even in the establishments for the education of the more wealthy classes, much improvement has taken place.

From the Reformation onward, when the Scriptures were first freely opened to all, no one believed that it was a necessary qualification for a Christian man or woman that he or she should be able to read the Scriptures. The oral instruction of the Church was thought all-sufficient in religion. To have an educated church, or an educated clergy, or an educated laity, was the object of those who most valued sound learning. The first colonists of New England founded a common school wherever they met to clear the forests and to cultivate the soil. The purpose of those schools was to teach; and it was from among the people educated by the Scriptures, who had been educated, who had been taught from the beginning of time, that the Reformation was to obtain support. When the Puritans came to this country, the idea of teaching the members of the congregation, especially of the children, to have a knowledge of the Scriptures, was the object of all persons. Neither the desire of education for the clergy, nor the desire of education for the laity, was taken for granted. Education was to be inculcated, to be urged, to be insisted on, and the education to be given was to be the education of the Scriptures. In no country in the world were the schools for the education of the people more necessary, more needed, than in this country. In no country in the world was the educational system of the nation more necessary, more needed, than in this country. The state of education of the people was the greatest need of the nation.

The education of the state was the education of the state. In no country in the world was the educational system of the nation more necessary, more needed, than in this country. In no country in the world was the educational system of the nation more necessary, more needed, than in this country. The state of education of the people was the greatest need of the nation. There was a system of education among them which they cherished and upheld. We live in another era, but it is not wise to let the people who are lost go by without realizing the necessity of the educational system of the nation.

There are four elements of the educational system in England, limiting the inquiry to that education which is woolly, or in part, gratuitous:—

1. Education by the Church, from the establishment of monastic institutions, till the Reformation.

2. Education by endowment, immediately subsequent to the Reformation, for the most part limited to schools for the higher branches of learning, called grammar-schools.

3. Education by the state, and especially after the Reform, when the state took the place of the Church, and the state became the educational system of the nation.

4. Education by voluntary associations, whether Sunday schools or day schools, some of which have, within a few years past, received a limited measure of assistance from the State.

The exclusive education by the Church has passed away. Education by the state never existed in England—even in the more restricted sense of state-counsel and small money. Neither the state nor the educational system of the nation ever existed in England. The educational system of the nation was the educational system of the nation. The state of education of the people was the greatest need of the nation. There was a system of education among them which they cherished and upheld. We live in another era, but it is not wise to let the people who are lost go by without realizing the necessity of the educational system of the nation.
bureaus out of the sons of the mechanics and the laborers; and many a man who had been a charity-boy in his native town, when he had risen to competence, pointed with an honest face to the institution which had made him what he was, and he drew his purse-strings to perpetuate for others the benefits which he had himself enjoyed.

According to the digests of the Reports made by the Commissioners for Inquiry into Charities presented in 1845, the annual income of the endowed schools-amongst which the mass of the schools mentioned by the Commissioners, in 1818. According to these returns the annual revenue of the endowed schools of England was 300,000£, to which if we add 7000£ for Wales, we have a very near approach to the revenue of the digest of 1842; the same returns state the number of endowed schools in England as 4107, and of children educated therein, 165,435; and in Wales, schools 209, children 7625. In 1853 a serious of questions was addressed to the overseers of the poor in England and Wales, the answers to which would show a falling-off in the number of endowed schools and children therein educated, giving the schools as 4106, and the children as 163,764. If there were such a fall ing-off, it may be accounted for by the fact that some of the endowed schools had been illegally converted into national schools. Computed from these measurements it is stated unanswerably that the revenue of the endowed schools was 300,000£, the number of schools 4000; and the number of scholars 150,000.

300,000£ thus derived from the rent of land, rent charges, funded securities, &c., during three centuries, has been the foundation upon which has been built up much of the sterling worth of the English character. One hundred and fifty thousand children have been receiving, for a long series of years, the most liberal and gratuitous education, some of the commoner rudiments of worldly knowledge, all of them religious instruction,—at an average cost of 2£. per child. The average cost of each scholar in the national schools is 11a. 2s. per annum. There have been many attempts, and some have been successful, to turn the funds of the endowed schools, contrary to the wills of their founders, into schools for universal education; and these attempts have been supported by the Court of Chancery, or encouraged by the legislature. But it has been found that the funds, upon the mortl武装 system, about 640,000 children, instead of 150,000. We apprehend that, with the best intentions, some unsound opinions have been taken up on the subject of endowed schools. The registrar-general, in his Report on National Education, says: "in many cases insufficiency of the national education is the more to be regretted, as the means of education exist, and the funds left for educational purposes, if properly applied, in the charities and public institutions, would, with some assistance from Parliament, supply the children of the poor with the sound knowledge which the scanty earnings of the parents do not enable them to purchase." We affirm that these funds are properly applied when they are applied to the precise objects for which they were intended. There have been abuses in the management of some of these institutions, which have been corrected. The Commissioners of Inquiry into Charities reported a vast amount of delinquency and neglect, especially with regard to grammar-schools. The Court of Chancery, upon the representations of the Commis sioners through the attorney-general, has remedied many of the most glaring evils; and we have now many institutions distributing a large measure of good, where formerly were only "Incompetency of the master," "School discontinued," "School non-existent," "Grammar-school abolished by trustees," "No free scholars taught,"—these are not uncommon statements amongst the original reports upon grammar-schools. But this is not the whole. Many of these abstracts and visitors at the present day would be ashamed of such gross misapplications of the means of preserving sound learning amongst the people. Legislative action has been brought to bear upon some; and the Harper Charity at Bedford, and Dalwich College, for which an Act was passed in 1857, now make their ample means much more generally advantageous. Abuses, no doubt, still exist; but, as a whole, the grammar schools have been a blessing to this country. They have been alive amongst us the liberal studies which have nourished a race of divines, lawyers, physicians, statesmen, that may challenge comparison with those of any nation. They have opened the gates of the higher employments to industry and talent; and we are assured from the Reports that they had mitigated the inequalities of society. They have ploughed up the subsoil of poverty to make the surface earthy and richer. What the grammar-schools have done for the higher and middle classes, the free schools have done for the lower, as a class. They have been a means of education for some boy who had no ambition, perhaps no talent, for the struggles of the scholar; they taught him what, amongst the wholly untaught, would give him a distinction and a preference to his worldly condition. If his children have been less fortunate, because they knew that there was no absolute bar to their children and their kindred running the same course.

Do we assert that there is nothing to be desired beyond this state of things? Unquestionably not. But we do desire that no feelings falsely called utilitarian, should induce us to wish the appropriation of funds to one purpose, that were appropriated to another purpose. An American writer, speaking of the property given to endowed schools, says: "It is easy to see that, if this sum were consolidated, and then applied to the support of liberal education, it would amount to an incomputable good." (Horace Mann’s Educational Tour, 1844.) The evil is computable, as well as the good. The good would be the education after some universal manner of 400,000 more children than are now educated out of these funds; the evil would be the education after the manner prescribed by the founders of these schools, and we think that the manner prescribed by the founders is more than ever necessary as education of some sort becomes more and more universal. We desire that the most arable land should be purchased to support a highly meritorious poor scholar by an exhibition at the university, than by leaving a thousand pounds to instruct fifty boys and girls in reading and writing. And why? The answer is the same as before: because a man is prepared for too large a share for individuals to deal with. They can more properly employ their charity in raising the character of education, by encouraging the higher branches of knowledge. The spirit of voluntary association, aided in a manner accurately calculated to its nature, may distribute millions. That spirit is not slumbering when we know—as we shall have to show in detail—that nearly 900,000 scholars are now receiving instruction more than the number that were instructed in 1855. These 900,000 scholars cost more for their annual instruction in addition to the cost of the schools which contain them—than the annual revenue of all the endowed schools that survived the Reformation, that have been founded since the Reformation, and which are continued in the service of education. This is the only systematic education which the people of England received up to the beginning of the present century.

Up to the year 1833 the legislature had limited its data with regard to education to inquiries into its state, and lamentations over its insufficiency. By the Acts of 1833 the principle was first established that it is just and wise to appropriate some portion of the public income to the purpose of education in England. Twenty thousand pounds were then voted, in aid of private subscriptions for the erection of schools, and in 17 places, of which they were the only systematic education which the people of England received up to the beginning of the present century.
opposition to this great measure, which had been adopted upon the responsibility of the executive government. The administration persevered in their plan, against a powerful minority in the House of Commons, and a vast majority in the House of Lords, who prayed Her Majesty to revoke the order. The House of Commons passed an address to the Crown, in which they expressed a regret that the Act had been appointed. The first parliamentary grant placed under the direction of the Council on Education was 30,000/, which was continued annually to 1843; it was then raised to 40,000/, for 1843 and 1844; in the session of 1844-45, it was increased to 150,000/; in 1845 and 1846, 150,000/; each year; in 1850, 110,000/; in 1851, 150,000/; in 1852, 160,000/; in 1853, 260,000/. In 1854, 263,000/; in 1855, 306,381l.; in 1856, 451,213l.; and in 1857, 641,203l.; a total since 1853 of 3,206,757l.

But there were other legislative actions, as well as plans to increase the grants of money. Without noticing the number of schemes proposed, and the debates upon them, in which the adherents of the voluntary principles, and those advocating a national superintendence and support, have contrived to neutralise each other’s efforts, we will shortly notice what has been actually done. In 1842 an Act was passed for facilitating the acquisition of sites for school-houses, which was repeated, amended, and extended in 1850, 1852, and 1853. In their attempt to remove and lessen those evils, and scientific purposes were exempted from the payment of county, borough, parochial, and other local rates; and in 1854 further facilities for the institution of such societies was afforded by another Act. In 1844, in a Poor-Law Amendment Act, the Church of England, as an established body, was combined parishes and unions into school districts, to form boards for their governance, which boards, subject to the regulations of the Commissioners, were to appoint, pay, and control its teachers and other officers, for the purpose of instruction; and the Act further provided that the minister was compelled to attend any religious service contrary to the principles of, or be instructed in any religious creed contrary to that professed by the parents; and in 1846 the provisions of the Act: were extended to provide for the support of schools not in unions, and removing the limitation of expense, previously limited to one-fifth of the aggregate of the poor-law expenditure. In 1847 the law regulating the attendance at school of children employed in print-works was amended. In 1850, an Act was passed empowering town-councils to establish public libraries and museums, by imposing a small rate, such libraries and museums to be open to the public free of expense; extended in 1858 to places not having councils and to parishes; and similar Acts were passed for Scotland and Ireland. While the Acts and Grants were continually bestowed on the subject of instruction the children of the honest poor, it was felt that there was a lower class, in which, probably to a great extent, ignorance and improvidence was the consequence; and it was resolved that some provision should be made to recall youthful vagrants or petty offenders to the paths of rectitude by judicious instruction; and after an experience of several years, both in England and Scotland, supported by voluntary contribututions, it was endeavoured to provide a benefit to those who were more numerous and were mostly neglected and rejected by the streets, and taught or trained, by the Charity, but to be recoverable from the parents, if able to pay. Other Acts, with the same object, were passed in 1856 and 1857, by the last of which justices of the peace in towns and boroughs, were empowered to order the instruction of any children received into their care, in their own houses, or in those of others, when they could not be found a place of education, and his careless or probably dissolute parents may be forced to contribute to his support.

Besides the above, which relate chiefly to those not entirely destitute, in England, an Act was passed in 1850 for amending the Ragged Schools Act, bringing under its provisions the parish poor-law schools, and by the Act, children of two years of age and over, but under sixteen, may be educated at the religious denominations of their parents, if the parents are willing to pay, or if the children are poor, be educated at the expense of the parish, and the Act also diverted a portion of the poor-law money to provide for this object. The Act also made a provision for those who, having been educated at the expense of the parish, should afterwards become destitute of any means of support, and in such case the parish would have the power of maintaining such children. In 1857 there was also passed an Act to make better Provision for the Care and Education of Ragrant, disturibute, and disorderly Children, and for the Extension of Industrial Schools. By this Act, without waiting any longer for the gazette to be printed, the Guardians of every parish, town, city, or other place of education, and his careless or probably dissolute parents may be forced to contribute to his support.

To Ireland the grants of money for the diffusion of education have also been large, and, on the whole, increasing. An Act for establishing Public Libraries and Museums in Ireland (18 & 19 Vict. c. 40) was passed in 1853; and a number of schools have been established, chiefly under the direction of the Roman Catholic clergy, to whom extent supply the place of Reformatory schools. The duty of licensing newspapers was assigned by the law in 1855, and the reduction of postage on printed papers, books, and MSS., may also be fairly considered as aids to education.

In addition to these and other legislative action, the general public have not been wanting in efforts to diffuse education. In most of the large towns Ragged Schools have been formed and supported for the instruction of the more destitute children; and, in conjunction with more school learning, it has been endeavored to provide for the public funds, for establish the shoe-blackbrigades and crossing sweepers, by which boys during the day are enabled to earn money, a part being devoted to their support, and the remainder placed to their account, to form a fund for their future advancement; their evenings being spent in school. The results, on the whole, have been very satisfactory. Schools have also been established for teaching girls Common Things, chiefly in domestic economy. The preparation of teachers has been one of the objects aimed at, and the means employed have been various, but, in the great number of schools, the young men and women, who are to be the teachers, are at present to be the guardians of the education of the children. The Reports of the Board of Education, and also by the above-named societies to visit their own; and in the Report of the British and Foreign School Society in 1857, one of them, Mr. William Chalmers Bannatyne, makes the kind of education given in most of our British schools some ten years ago, it is with ordinary gratification that I observe the vast improvement that has been effected, both in the expense and in the method of teaching it."  

The Report, in 1854, of Mr. Horace Mann on Education, compiled upon the materials furnished by the census of 1851, confirms this. He states that there were then 40 colleges, supported at an annual cost of 80,000l.; and that from five belonging to the National School Society, 527 qualified teachers issue annually. By the whole about 400 masters and 320 mistresses are annually prepared for their duties.

Looking then, to the prodigious exertions that have been made since 1833, we may conclude that from official returns we should find such an increase of school accommodation, and of children under instruction, as would leave little to be done beyond a steady perseverance in the same course of affairs. In 1843, the government’s policy was considered with reference only to the numerical amount of education; the quality of the education given embraces a much wider range of inquiry. Important as it is to ascer tain with exactness the number of children daily receiving instruction by the aid of voluntary societies, it is not possible to know the means of such computation are not yet perfect; and the computations of those who take different views as to the necessity of State interference are so widely different, that it requires a very careful analysis, and, what is more, a complete abnegation of the spirit of partisanship, to enable us to arrive at safe conclusions.

The Rev. Mr. Hook, in a pamphlet published in 1846, calculated that for the proper instruction of the people, one in every 20,000 is required to be educated at school. Some enthusiasts say the proportion should be one in five. E. Baines in 1845 estimated that one in every nine was then at school. Mr. Mann, in his Report, thinks that one in eight would be sufficient for all useful purposes. In 1833, in a population of 14,100,000, the number of day scholars was 1,276,047, which gives one in every 11.27; and of Sunday schools, of 1,645,800, or one in 9.28; the total is 2,920,337, or one in every 5.02. But to include the Sunday schools would be a fallacy; for the instruction, though extensively given, only includes reading, and has led to much reading as to enable children to read their Bible and a few other religious books, and many of the children are also attendants at day schools. By the census of 1841 the number of children between five and fifteen years of age, in a period during which the greatest numbers were making the conclusion of their school education, was, in round numbers,
The term 'scholar' may have been loosely understood, but the probability is that all were being taught something. Of the number in the census return 303,348 were boys and 183,169 were girls, attending at 5942 schools. At public day schools there were 280,046 scholars, and at private day schools 113,302 scholars, of which, however, the census includes all persons at school, and that of the 286,611 of whose teaching accounts were obtained, 17,766 were from fifteen to twenty and upwards. This would reduce the comparative number with England to 268,845, one in every 4.8. Sunday school returns are not so much frequented as in England. At the time of the census there were 295,545 scholars, or little more than one in ten of the population. At adult evening schools there were 324,987, of which 243,369 were boys and 81,618 were girls.

Of the total number of boys in the public day schools, out of 115,028 of whom information was given, 134,327 were being taught reading, 53,005 writing, 68,174 arithmetic, 42,322 English grammar, 48,508 geography, 6770 modern languages, 9111 ancient languages, 6400 mathematics, 4197 drawing, 31,857 music, and 1092 industrial occupations. Of 115,028 girls in public day schools, 98,612 were being taught reading, 51,880 writing, 43,483 arithmetic, 24,435 English grammar, 28,279 geography, 3990 modern languages, 3060 ancient languages, 5590 mathematics, 3093 drawing, 25,139 music, and 2013 industrial occupations. The proportions are nearly the same in the private day schools. We may remark, however, that in the parochial schools music only means the singing of psalms, and of English songs; in Scotland, only the number of schools in which such subjects are professed to be taught. In Scotland the average yearly salary of the parochial master is 25s., with, in general, a residence; of the mistresses the salary is 16s., with a residence and income. Of course, the object in the last-named religious establishment is the instruction of parochial schoolmasters, but the improvement was not, as is shown by the census returns.

In Ireland the endeavours to promote education have been constant, but till lately very ill-applied. Under Henry VIII. an Act was passed that every family should send one child to an English tongue to all in his cure. By the 12 Eliz. cap. 1 (1570), a free school was to be established in every diocese. The statute of Henry VIII. was re-enacted under William III. of Scotland. There were more children taught in the year 1760 than in 1725, and it is supposed that Protestantism should be taught; of course the schools were ineffective; and almost of course they became a mere form, the clergyman giving forty shillings a year to some one called a schoolmaster, and taking no further trouble. In 1731 the Incorporated Society for Promoting English Protestant Schools in Ireland was established, and was liberally assisted from the public funds. In 1741 they had formed 5 schools, at which they had educated 372 children (who were digital and lately were increased to 1388). In 1767 the annual income was 9070, or 10,000. These were the Charter Schools. In 1768, after an expenditure of 499,000, the celebrated John Howard proved that the children were ill-treated, their education neglected, and that they were made to work for their masters, and were thus deprived of the years of life that should have been devoted to the purpose of conversion. The Irish House of Commons admitted the facts, but continued to vote money. In 1808 orphans and children of Protestants were admitted as well as Roman Catholics, but with the same separation from the families as before. The number of scholars increased, they were still under 1000, and the annual cost was 35,000, of which sum three-fourths were paid by the State. After a report on their condition in 1825, the government support was suspended, but the schools were opened; though utterly failed, the Irish poor were far from being an uneducated people. There were 'Hedge' schools, where the children of the peasantry were taught by the priest so effectually that Weikfield in his 'Forty Years in Ireland' calls the Irish 'universally educated' people. In 1817 the Kilclare Parochial Society began their operations. They were to form two model-schools in Kilkare Place; they were to assist with grants the founding of schools; to receive and qualify masters; to teach and assist in making proper books; to cause the schools to be inspected annually; and to encourage deserving masters and mistresses by gratuities. These schools were at first a success. They were supported by government grants, and were tended by ancients. In 1825 they had 1490 schools, and upwards of 100,000 scholars, but their length became distasteful to the Roman Catholics. In 1831, therefore, after a Parliamentary inquiry, a Board of

3,620,000, leaving nearly 800,000 unprovided for. But among the industrious and working classes comparatively few can afford to keep their children at school till they are fifteen, and the far greater portion will only be at school for periods of four or five years, or even less. It is not easy to test the amount of the public aid that is required. In 1372-3, 30,886 men and 25,037 women were married. In 1383-4, out of 121,028 marriages, 40,557 men and 58,959 women signed the register with marks, so that only 59.5 per cent of the males could write, and only 41.1 of the women. In 1531 the total number of children between five and fifteen, was 4,005,718. But, probably from the extension of infant schools, it was found by the census that a large number of children were sent to school at the ages of three and four, and therefore the number between three and fifteen in 1531, was 105,711 children. Of whom 56,461 were boys and 49,242 girls. Of this number, beginning at five years old, 381,774 boys and 218,055 girls were employed. Between five and ten, upwards of 2000 boys are messengers; nearly 2000 are farm labourers; upwards of 5000 boys and 7000 girls are engaged in the cotton and woollen manufactories and in straw-plaiting; and 1209 boys and 11 girls in coal-mining. Between ten and fifteen the numbers employed in nearly every profession become very large, showing that this age is the most useful; but for the greater part of the period of education, the ordinary term seldom extends beyond twelve or thirteen. The demand for juvenile labour, and the prospect in a labourer's family of gaining an additional income, is an inducement which will probably be sufficient to overcome the prospective advantage of sending the children to a school, where the instruction gives little promise of promoting the child's pecuniary interest. To the number thus withdrawn from school, must be added a considerable number of those who, from the exigency of the five years and ten, is separated from the parents by themselves: the returns give 17,308 boys and 27,323 females, which there is little doubt represent those having teachers. Deducting these classes, we have 4,264,243 children who ought to be provided with the means of education. Though illiterate, every year every great attention, yet it is not likely to be continuous through the period, we make no deduction on that account. To supply the want, the census return shows an attendance of scholars in day schools in 1836, a proportion of one in eight of the population, but little more than half of the number of children. The Sunday schools make an addition of 3,407,649, which carries the number above what is required; many, however, of the younger day-schoolers attend them, and some of the employed may attend, but, as we have said, the education afforded at these schools is inefficient for practical purposes.

The Report gives a table showing the number of scholars for each county, between three and fifteen, by which it would appear that the average attendance of scholars between their third and fifteenth year is five years, and between five and fourteen, four and two-fifths. What a child can learn from three years old to eight cannot be much, supposing they are all at school, and certainly not during the five years and ten, which is the age at which they leave school, and is almost certainly lost when subsequently employed in labour, without the aid of secondary schools to keep their scholastic acquisitions in use. This is shown by the marriage registers for 1836, in which, out of 604,526 persons married, 44,806 men and 62,672 women signed with marks, or 34 per cent of the whole. This is certainly a great advance on 1833, but as in the last eighteen years such great efforts have been made, a more satisfactory result might have been expected. If the whole of the greater part of this number of people must have received their education before the most material improvements had been introduced. Great part of what we have written applies equally to Scotland and Ireland. Scotland shares in the Parliamentary grants we have enumerated, and has also adopted most of the extensions of school education we have mentioned. On the whole, in that country education is more widely diffused than in England, and in the parochial schools it is of a much better class. Of the five years and ten, the greater part of the money received from the Government, and from the private endowments, is expended in providing instruction; and mathematics and Latin, with occasionally Greek, is taught where the scholars are capable and desirous of receiving such instruction. In 1831, the population of Scotland was 2,385,674, and by the return, the number of scholars was 368,517, or one scholar to every 7.84 inhabitants, but under the heading of `Occupations,' the number returned as `scholars' was 426,568, or one in every 5.87. In the latter number

"SCH"
National Education in Ireland was established, composed of eminent men from all the religious beliefs in Ireland, who were commissioned to draw up a scheme of instruction, and provided that the children of all creeds should attend. This was done very successfully. The government were liberal in their grants; and at the close of 1833 they had established 789 schools which were attended by 107,116 scholars. These schools continued to thrive, and the number of scholars increased to 1852, where there were 120,000 annually; in 1851, 134,566; in 1852, 164,577; in 1853, 189,073; in 1854, 163,400; in 1855, 213,260; in 1856, 297,041; and in 1857, 328,849. The number of scholars attending the schools, in consequence of the large emigration of the few preceding years. The census returns of 1851, however, tell a very unsatisfactory tale. The total population of Ireland was 6,618,761; the number of males who could neither read nor write was 1,102,650; of the females, 1,953,633.

But in that year the number of the National Society schools had increased to 4704, there were 94 in progress of erection, and 13 had been completed. The number of children on the rolls was 260,451; there had been 257 teachers trained in the school during the year, and 33 at their own expense. Of the 290, there were 21 of the Established Church, 39 Presbyterians, 2 other Protestant Dissenters, and 290 Roman Catholics. The new schools, besides being free religious schools, with 303 pupils, of whom most must pay either fully or in part. On Dec. 31, 1855, the number of schools was 5193, and the number of children on the rolls was 638,446, a decrease from 1854 (up to which year the number had been continually increasing), an unfortunate feeling of dislike taken to the schools by the Roman Catholic priesthood, and partly from the large emigration that had taken place from the kingdom. In 1856 the annual report of the Church Education Society claimed 90,572 scholars, but these include "schools in connection," and in 1851, under the same heading, they numbered 105,878 scholars. The Sunday schools in 1855 mustered 213,019 scholars.

The 2nd Act was passed for endowing Maynooth College for the better education of the Roman Catholic priesthood. In the same year was also passed an Act "enabling her Majesty to endow new Colleges," in consequence of which the Queen's Colleges of Belfast, Cork, and Galway have been established. A sum of 10,000/. was assigned out of the Consolidated Fund for purchasing the sites, and erecting and furnishing the buildings of the three Colleges. Her Majesty and her successors were made proprietors of the same; and the funds for the same purposes were vested in the Crown for the purpose of executing the office. The appointment of the presidents, vice-presidents, and professors, was entrusted to the Crown, until parliament should otherwise determine. The Commissioners of the Treasury were empowered to issue annually a sum of 150,000/., as a foundation stock, for the erection of buildings, for the payment of salaries, and for the other expenses in each college; it being moreover provided that reasonable fees should be exigible from the students. Lecture-rooms were directed to be assigned for religious instruction; and it was enacted that no student should be allowed to attend any of the colleges unless he should reside with his parent or guardian, or some near relation, or with a tutor or master of a boarding-house licensed by the president, or in a hall founded and endowed for the reception of students.

A president and vice-president for each college were soon after nominated, and the erection of the buildings was begun. The other appointments were made in August 1849, and the three colleges were opened in the end of October following. The annual sum of 12,000/. had shortly before been granted by Parliament for providing them with libraries, philosophical instruments, and some other requisites.

Originally it was intended that the number of professors in each college, exclusive of the president and vice-president, should not exceed twelve, and letters patent constituting them upon that basis were passed for each under the great seal of Ireland in December 1845. Afterwards it was determined that the number should be augmented for the present to thirty. The annual sum of 12,000/. had been granted by Parliament for the salaries of these professors. The vice-president however is also a professor. New letters patent embodying that extended scheme were granted in favour of each of the three colleges in November 1849.

A rising constitution, then, the body politic and corporate of each college consists of a president, with a

salary of 800/. and a house; a vice-president, with a salary of 500/. and a house; and professors of Greek, Latin, mathematics, history, and English literature, logic and metaphysics, chemistry, mathematics, astronomy, physics (with a salary of 250/.), modern languages, natural history, mineralogy and geology (each with a salary of 200/.), English law, jurisprudence, and political economy, civil engineering, and agriculture (each with a salary of 150.), the Celtic languages, the practice of divinity, and the law of entail and mortmain (each with a salary of 100.). There are also attached to each college a registrar (with a salary of 200/), and a bursar and librarian (each with a salary of 150.). A sum of 300/. is also granted for the payment of clerks of post and servants. The total annual expenditure for salaries is thus (deducting 200/ for the professorship held by the vice-president) 5500/.

The remaining 1300/ of the annual charge on the consolidated fund for the number of males who could neither read nor write was 1,102,650; of the females, 1,953,633.

The scholarships awarded at the commencement of the session at Belfast are: of 48 each to students of the faculty of arts; of 40 each to students of the faculty of medicine; of 20 each to students of the faculty of law; 20 each to students of civil engineering; and of 15 each to students of agriculture; the number being equally divided in all cases between students of the first and students of the second year. The scholarships awarded at the commencement of the year at Cork are:

The session in all the colleges extends from the third Tuesday in October to the second Saturday in June, and is divided into three terms by recesses of a fortnight at Christmas and at Easter. The fees for each class vary from 11 to 2110/; and an additional fee is charged to each regular and settled student to the bursar on behalf of the college of 3l. at the commencement of the first year, and 2l. at the commencement of every subsequent year.

It had been all along contemplated that matriculation and attendance at these colleges, as at similar institutions established by public authority in our own and other countries, should conduct to graduation both in arts and in every other faculty, except only that of divinity; and all the regulations and arrangements of the several institutions have been moulded upon that understanding. It was a question however we believe, for a considerable time whether, with a view to the conferring of degrees and other purposes, each college should be erected into a distinct university, or the three constituted into one university. The latter plan has been adopted, undoubtedly to the placing of the new establishments in a greatly superior position to what they would have held if they had been left each to itself. It was agreed that a mere Belfast, or Galway degree would have carried the same weight with one from the Queen's University in Ireland. In the letters patent creating such a university, her Majesty has declared that the graduates of our said University shall be full members of all the learned societies, and that all the immunities as belong to persons holding similar degrees granted them by other universities, and shall be entitled to whatever rank and precedence is derived from similar degrees granted by other universities.

The peculiarity of and the need for such colleges arose from the state of religious feeling in Ireland. The greatest proportion of the people are Roman Catholics, and there is a large number of Presbyterians: but in Trinity College, Dublin, there are no arrangements which either recognize the existence of any form of religious belief but that of the Established Church; not only is the student who may hold any other creed (in so far as such dissenting students are admitted, at all) left without any spiritual superintendence whatsoever, but the entire system of teaching and discipline is in the hands of members of the Church established by law, and is regulated and administered in all respects in conformity with the doctrines and ritual of that Church. Freedom of admission to Oxford and Cambridge has long been one of the demands which Protestant Dissenters have urged most clamorously. Notwithstanding considerable opposition the experiment has succeeded. The colleges are filling with all the religious creeds; but while thus free to all, the morals and the peculiar faith of the student is sedulously attended to.

Neither in England have the efforts to promote education been confined to the poor. At Durham the bishop and dean and chapter obtained an Act of Parliament in 1639, authorizing the institution and endowment of a university,
which was opened for students in October 1833. In 1837 a royal commission was obtained by which the style and title of the Warden, Masters, and Scholars of the University of Durham was given to the institution. The charter gave the power of conferring degrees, and confirmed the rights and privileges annexed to it by Act of Parliament, naturally enjoyed by charter. The bishop is appointed visitor; the dean of Durham is constituted warden. To the professorships of divinity and ecclesiastical history and of Greek and classical literature, which are both in the patronage of the bishop, canons in the cathedral are appointed. In the same manner of mathematics, the reader in law, Hebrew, history and polite literature, and natural philosophy, the lecturer in chemistry and mineralogy, and other offices of the university, are appointed by the dean and chapter. Of University College, the Rector of the dean of the University of Durham; Bishop Hatfield's Hall, instituted in 1846, is for divinity students. It has four tutors, one of whom is principal, a censor, and a chaplain. The academical year consists of three terms of not less than eight weeks each, which are called Michaelmas, Epiphany, and Easter Terms. The age of admission to the academical course is from 16 to 21; and for the divinity course, between 21 and 26; beyond this age students must be admitted by special leave. Care has been taken that the necessary expenses of students should be moderate as compared with the income of their parents, and any approach to extravagance is sedulously guarded against.

In 1834 an Act of Parliament extended the right enjoyed by the graduates of Oxford and Cambridge to practise physic without a licence, and also to the graduates of the University of London. In the same year by another Act, a commission was appointed to draw up regulations for the improvement of Oxford University, and in 1837 a similar one was passed for Cambridge. Under these regulations valuable improvements have been effected, and more may be confidently expected. Among those effected are the breaking up of the close scholarships (especially those of Winchester school) and throwing them open to general competition, the establishment of a numerous number of prizes, the creation of a number of new censors, and the abolition of the oath on matriculation and on taking the degree of B.A.; by which last regulation Dissenters are admitted to the whole advantages of a university education. In Scotland also an agitation is being made for some improvement in the universities.

SCHOLAR. [Toursman.]

Schumacher, Heinrich Christian, was born on Nov. 16, 1780, at Bramstall in Belgium. He distinguished himself by his mathematical proficiency and by his predilection for astronomy. At the age of thirty he was created professor-extraordinary of astronomy in the university of Copenhagen, whence he was called in 1813 to be director of the observatory, a post which he held until 1815 as professor of astronomy and director of the observatory there. In 1817 he was employed by the Danish government to measure the degree of longitude from Copenhagen to the west coast of Jutland, and the distance of latitude from Skagen, the northern cape of Jutland, to Lauenburg, on the frontiers of Hanover; afterwards continued through Hanover by Gauss. In 1821 he received from the Royal Scientific Society of Copenhagen the direction of the survey and mapping of Holstein and Lauenburg; and in that year the king caused a small but excellently furnished observatory to be built for him at Altona, where he resided till his death. In 1824, in conjunction with the English Board of Longitude, he fixed the measure of difference between the observatories of Greenwich and Altona, for which purpose the English admirably furnished a steam- vessel, provided with twenty-eight English and eight Danish chronometers. In 1830 he was employed in ascertaining the length of the seconds' pendulum at Copenhagen, and made the base of the Danish scale of measures. In 1813 he commenced a work, 'Astronomische Nachrichten,' a work that is still continued, and is the only one that serves as a vehicle for the communication of opinions and facts from the astronomers of all the world. In 1826 he published a second volume of this. From 1829 to 1829 he published his 'Astronomische Hütten,

a'certainly of a carefully calculated ephemera. In 1830 in conjunction with Bessel he undertook the editing of another Astronomische Jahrbücher. He was a diligent and correct observer; in 1836 he announced the exact distances of Venus, Jupiter, Mars, and Saturn from the earth; and the phenomenon connected with Encke's planet Atra was noticed in this by the older part of his life. He died at Altona on December 29, 1850. Schumacher united great talents with much modesty. He enjoyed the confidence of his sovereign, which he repaid by his diligent services, and he uniformly treated his fellow-labourers with the greatest kindness and impartiality with unostentatious liberality.

Schumann, Robert, a composer who has a great reputation in Germany, but whose works are little known in this country. He was born about the year 1814, and spent about ten years in the study and practice of his art. His excessive application disordered his mind; and when he died, July 29, 1856, he had been several years the inmate of a lunatic asylum. He was for a time a private groomsman of the prince who, on the day, who, with several children, survives him. Schumann was undoubtedly a man of great genius; but he has injured his reputation with his contemerals by his endeavours to found a musical school, or sect, professing to disregard the authority of the older masters, and to establish a new system of musical composition. As music has always been in a progressive state, posterity may perhaps do him justice by adopting his innovations of style. His only work of magnitude which has been publicly performed in England is a cantata, 'Wilhelm Meisters Tod,' the composition of a part of Moore's poem. It was produced at one of the Philharmonic Society's concerts in 1836; when the principal part was sung by Madame Goldschmidt (Jenny Lind); and, though our critics were at variance respecting its merits, it was generally regarded as a work of no ordinary powers and beauty.

Schwanthaler, Ludwig Michael, one of the most eminent of modern German sculptors, was born at Munich in 1802. For some generations his ancestors had been sculptors in the Tyrol; his father, Franz Schwanthaler, was settled in Munich, where he acquired a very respectable standing as a monumental sculptor. Ludwig received a good classical and general education; he was desirous of being initiated into the arts of drawing and modelling, and the use of the chisel, in his father's studio. At the Munich Academy of the Fine Arts he was regarded with coldness; if not unlike on account of his free notions in art, by Von Langer the director, who is said to have urged his friends to dissuade him from going to some other profession. The death of his father in 1831, by rendering it necessary that he should conduct the business for the maintenance of the family, fixed his destiny as a sculptor. A commission was given him from the King; the prospect of making himself known was one from the King Maximilian Joseph in 1824, to design a centre ornament for the table. It was to be of very large size, and the figures in relief, each about six inches in height, were to represent the nine divinities of the Roman Temple of Jupiter. So much as was executed in described as being very beautiful, but the death of Maximilian (October 1825) prevented its completion.

Schwanthaler now proceeded to Rome, where he remained a year, deriving great benefit from the advice and friendship of Thorwaldsen. He carried back with him to Munich two elegant bassi-relievi of the 'Birth of Venus,' and 'Cupid and Psyche,' and through the influence of Cornelius he was employed to execute two vast freize ofy great basi-relievi of the Glyptothek, then in course of completion. Among other works which about this time he produced we must mention a statue of Shakspeare for the theatre, and a grand bas-relievi of the Iliad, consisting in all to a length of 150 feet, of the Apotheosis of Burgundy for the dining-room of the palace of Jupiter. In 1838 he again went by desire of King Ludwig to Rome, to complete Rauch's design for the south pediment of the Walhalls as well as to execute various other royal commissions for the new palace.

The story of Schwanthaler's life was one of incessant activity. The admitted head of the sculptors of Munich, the professor of sculpture (from 1835) in the Academy there, and the favourite of the art-loving King; he employed himself in the execution of innumerable important commissions of all kinds. From 1835 to 1840 he was engaged in the planning and working-out of the sculpture of the Romantic school, a vast architectural undertaking. Schwanthaler produced in rapid succession an astonishing number of works of annual magnitude and grandeur, and was the centre of a crowd of able and devoted scholars and assistants. For the few remaining years of his life, all spent in ill health, he limited himself to the management of the work and the personal superintendence of the artists. The magnum opus of Schwanthaler was the workshop of the Academy, which was completed in 1864. He died at Munich on December 11, 1863, about a year before its completion. Schwanthaler was a man of remarkable versatility and ability. He had a vast store of knowledge; he was at once a good draughtsman, a skilful sculptor, and a fine draughtsman. He had a remarkable power of executing the most intricate work with the greatest ease and facility; he was a master of a pleasing and studied style. He had a fine sense of beauty, but was prevented from making the best use of it by his excessive and constant application, which disordered his mind and finally brought it to an end. His statue of Goethe is one of the most remarkable of modern art: it is considerable for its grandeur and simplicity, and is a model of what a great master might have done if he had not been so constantly engaged in the execution of large and complicated works.
executed a succession of great works, such as would seem more than enough to have tasked the energy and industry of the most indefatigable and laborious workman whose days had been extended to the longest span, and who had been blessed with the most robust health.

We can name but some of his more prominent works. The southern pediment of the Walhalla at Ratisbon, filled with the intention to typify the liberation of Germany from the French yoke, is a very striking example of the northern pediment, a later work, was wholly by himself, and was of a much higher order of merit. It is called the ‘Hermann-Schacht,’ or ‘Battle of Arminias,’ and is one of the most characteristic and noble productions from the chisel. It has never been rivalled by the sculptor’s chisel. He also executed some of the statues in the Walhalla, and the fourteen carvings representing the Walkyren of the Teutonic mythology.

For Ludwig’s New Palace (Nene Königsland), Schwant- thaler not only adorned several floors but also, and he made the cartoons for numerous pictures which were painted in encaustic by Hiltensperger, Streidel, and others. Among these are a series of twenty-four compositions by Zschokhn, twenty-one from Sophocles, twenty-seven from Aristophanes, a series from the tales of the Argonauts, another from the ‘Works and Days’ and the ‘Shield of Heracles’ of Hesiod. His most famous piece of sculpture here is however the ‘Myth of Aphrodite,’ but the story of Venus was never more colorfully enacted. A fantastic story of Feist-Saalan he designed and the eight figures represent various heroes and virtues of Bavaria, on the entablature; the frieze in relief of the ‘Crusade of Barbarossa’ (‘Der Kreuzzug des Kaisers Friedrich Barbarossa’), placed above the paintings by Schnorr [Senners, etc.]; others. Of the many statues that come to mind, the host of Greek Dancers in the Ball-Room; and the twelve colossal gilt bronze statues of the princes of the House of Wittelsbach, in the Throne-Room, etc. For the façade of the Franekoth he executed statues of twenty-five of the greatest painters. For the entrance of the New Art-Exhibition Gallery (Neue Kunststellungs-Gebäude) he executed a representation of the Arts placing themselves under the protection of Bavaria. For the magnificent Ludwig Kirche he executed statues of Christ and the four Evangelists, which are placed above the entrance; and, for the ends of the gable two colossal statues of St. Peter and St. Paul. There are also by him in Munich statues, some of them colossal size, and most of them in bronze, of Count Tilly, Field-Marshal Prince Wrede, Kreitmayer, the author of the Bavarian code, and one or two others. But the chief work with which he adorned his native city was his immense statue of Bavaria, which occupies the centre of the Bavarian Hall of Fame (Bairische Ruhmeshalle). Bavaria is repre- sented as the personification of his land, her back is stretched out, and holds a laurel crown, the reward of merit; the other presses a sword against her bosom, to defend her independence; by her side rears a lion. The group, which is of bronze, exceeds in magnitude any other work in Munich, and even in Germany; the tail of the lion is near 30 feet; the pedestal is 28 feet high; a staircase inside leads up to the head of Bavaria, which is large enough to contain several persons. This vast work was commenced in 1844, but neither the sculptor nor the founder of this unparalleled work [Stölzel, Johann Baptist, S. 1], lived to see it placed on its pedestal. It was inaugurated with great ceremony, October 9, 1860. Remark- able as this work is for its size, it is equally so for its unrivalled beauty. It was the first instance of its kind, and as long as it endures it will be the most impressive monument to his genius. The Ruhmeshalle however con- tains other proofs of his versatile imagination. In the ympas on the end of the wings of the building are four colossal representations of the four capitals and peripheries of the kingdom; Bavaria, the Palatinate, Swabia, and Franconia; and the frieze contains 92 metopes, all of them designed by him; 44 containing figures of Victory, 28 the remaining 45 the arts and occupations of civilised life.

Among important public works which he designed for other places may be mentioned, his grand fountain in the Vomarkt, Vienna, around the basin of which he placed a representation of the allegories in the fountains at Munich; and principal rivers of the archduchy of Austria, pouring their waters into the Danube, which is represented by a colossal gry in the centre; another and finer fountain in the Ringen, Vienna, in which are five beautifully designed bronze figures of Austria with her four great rivers, the Danube, Vistula, Elbe, and Po; the monument of Carl Friedrich, grand-duke of Baden, with its four allegorical statues, at Carlthe, monument of Gustav Adolf on the lower Bornen, at Bremen, a colossal statue of a merchant, from the Teutonic mythology; statues and statuettes of knights and old Teutonic heroes; and a vast number of sepulchral and portrait statues, busts, and medallions, which are to be found not merely in the princely galleries and churches of Bavaria and Austria, but scattered throughout Germany, and occasionally in England.

Ludwig Schwanthaler died—his feeble frame, it is said, literally worn out by his incessant labour—on the 17th of November, 1845, having only a few months before completed his forty-sixth year. The above very incomplete enum- ration of his works will more than suffice to show the won- derful energy and industry of the man; but it is necessary to examine the works themselves to form a just estimate of his genius; for there are various instances in which he has been less successful. It is not of course be supposed however that he accomplished the impossible task of carving all these works with his own chisel. From the establishment of his studio at Munich he had about him a large body of pupils, some of whom have been or are to be mentioned here under various heads. Scarcely a portrait or relief that has been executed in the Teutonic landed states has not been designed by him, or is in any other way connected with him.

By his will Schwanthaler bequeathed to the Munich Aca- demy of the Fine Arts his studio, with models of all the principal works executed by him. The studio stands oppo- site to the house in which he died, in the street named in his honour as Schwanthaler Street. Many of his pupils have preserved the extensive collection of his works. It is open daily to the public, and is one of the great art-sights of the German metropolis of art. The Crystal Palace at Sydenham contains casts of the head of the colossal Bavaria, the ‘Shield of Hercules,’ and several other of Schwanthaler’s productions.

SCIENCE AND ART, DEPARTMENT OF. This department of the Committee of Privy Council on Education owes its origin to the suggestions contained in the Second Report of the Commissioners for the Exhibition of 1851. After rong the necessity of the industrial classes of this country receiving more systematic instruction in science and art in order to enable them to maintain their pre-emience among manufacturing nations, the government pressed on the government the advantages which would result from bringing the various institutions connected with science and art that were supported by the public funds, into close connection with each other, instead of their re- maining under different departments of the government. The government took a favourable view of the suggestion; and as a part of the "comprehensive scheme for the advancement of the fine arts and of practical science," announced from the throne in 1852, the Home Secretary was empowered to negotiate with the different holders of the public funds, the Lords of the Treasury, in March 1853, gave their formal concurrence to the proposed arrangement of the Privy Council to "unite in one department, under the Board of Trade, with the Departments of Practical Art and Science, the kindred and the Geological, and the Art and Science, the Museum of Practical Geology, the Geological Survey, the Museum of Irish Industry, and the Royal Dublin Society, all of which are in part supported by Parliamentary grants;" and, the Treasury minute proceeds, "my Lords have
given directions that the estimates for all these institutions shall be brought together under the general head of Board of Trade Department of Science and Art." The immediate purpose of this amalgamation, it was declared, was to bring the whole of these institutions under one common superintendence, to establish a central metropolitan school of practical science as well as of art, and to encourage and extend the formation of minor local institutions which should be in connection with the institutions by the central institutions, to be not only self-supporting and under the management of the local authorities.

As was above said, the institutions thus brought together under one department, were all in part supported by Parliament. It was voted for the previous year, in connection with the amalgamation were: Government School of Mines and Science, 800L.; Museum of Practical Geology, 5572L.; Geological Survey, 5500L.; Museum of Irish Industry, 3348L.; Royal Dublin Society, 6540L.; Department of Practical Art, including the Provincial Schools of Design, 17,920L.; in all 39,181L.; but the sum actually granted was 41,582L., additions having been sanctioned of 150L. to the School of Mines, and 5256L. to the Department of Practical Art.

Of these institutions the character may be briefly indicated. The Government School of Mines and of Science applied to the Arts was founded in 1831, in consequence of memorials addressed to government by the mining districts of the United Kingdom, in which it was shown that the schools for the training of mining experts which had been established in various Continental governments had much increased the economy, efficiency, and safety of mining operations in the countries in which they had been established, and that the want existed here of such establishments as would include the mining districts of this kingdom. The Government School of Mines was accordingly opened in connection with the Museum of Practical Geology in 1851. It is now merged in the Metropolitan School of Science applied to Mining and the Arts, which forms one of the two main branches of the department which is the subject of this article.

The origin and purpose of the Museum of Practical Geology were stated under the head Museum of Economic Geology, S. 1 (vol. p. 460), and it will be enough to add here, that it was in 1850 that a Museum of Practical Geology was opened in Jermyn Street, St. James's—now the head quarters of the Metropolitan School of Science. Ever since the establishment of the Museum, the Geological Survey of the United Kingdom has been carried on in connection with it, and thus extensive collections have been formed, and are continually augmenting, illustrative of the structure of the British Islands, and of the applications of geology to the useful purpose of life. The geological survey has been proceeding since the establishment of the University of London, being of course divided between England and Ireland which has advanced far towards completion. In Scotland it has, however, made but little progress owing to the maps of the Ordnance Survey of Scotland having been only partly issued.

Of these metropolitan scientific institutions we may add the Royal College of Chemistry, founded in 1845, it having been, in 1853, transferred to the Department of Science and Art.

The Department of Practical Art was a development, or rather reconstitution of the central Schools of Design of which a full account is given under Design, Schools of, vol. 1 (p. 473). The Department of Practical Art was created by an Act in 1852, which amalgamated with the other institutions in the Department of Science and Art, and before it had come into full operation as a separate institution.

The Royal Dublin Society for the Improvement of Husbandry, Manufactures, and other useful Arts and Sciences, was founded in 1731, and incorporated by royal charter in 1749. It possesses a valuable museum of natural history, an agricultural museum; an excellent library; a museum of sculpture, casts, &c. From its establishment, we believe, it has been in full sympathy with the art and science which were in advance of its time; and before it had come into full operation as a separate institution. The Royal Dublin Society for the Improvement of Husbandry, Manufactures, and other useful Arts and Sciences, was founded in 1731, and incorporated by royal charter in 1749. It possesses a valuable museum of natural history, an agricultural museum; an excellent library; a museum of sculpture, casts, &c. From its establishment, we believe, it has been in full sympathy with the art and science which were in advance of its time; and before it had come into full operation as a separate institution. From its establishment, we believe, it has been in full sympathy with the art and science which were in advance of its time; and before it had come into full operation as a separate institution.
on admission. Several exhibitions have been founded, to be competed for by matriculated students. The lectures are open to occasional or non-matriculated students, on payment of a higher fee; and special short courses of evening lectures, at an extremely low fee, are given every session to working men only, and are attended always by as large a number (500) of diligent students of that class as the theatre will hold.

The Metropolitan School of Science enjoys rare advantages from the ready access which the students have to the treasures accumulated in the Museum at Jermyn Street. These, as was said above, consist of the extensive and admirably arranged geological collection formed during the progress of the Geological Survey of the United Kingdom, "illuminative of the structure of the British islands, and of the applications of geology to the useful purposes of life," under the able directors and indefatigable staff of the Survey. To these has been added a considerable number of mining tools, and working models of mining machinery; and of tools, and models, and specimens of machinery for general purposes. The Museum is open gratis to the public during five days of the week.

The maps and sections of the Geological Survey, and a large collection of plans and sections of mines, &c., belonging to the Mining Record Office, are deposited in the building at Jermyn Street. The chemical laboratories are those of the Royal Institution. They are open to the examination of all the members of the School. There is also a collection of stained-glass windows purchased by the School, which will be exhibited when they are bound. The collections were of the property of the Government. In connection with the Metropolitan School of Science, Cottonier to qualify students for examination in the Degree of Bachelor of Science since 1858 in several of the large manufacturing, mining, and chemical industries. These schools—which there are, we believe, nine in operation—in accordance with the principle laid down by the government on the formation of the Department of Science and Art, are in a great measure self-supporting, the Department exercising a certain amount of control, and, in return, affording a limited pecuniary aid to certified masters of the schools. According to Dr. Playfair, the Chief Inspector of Science Schools, and Scientific Referee of the Department, the schoolmasters are "an essential element of the working of the educational system, and the disposition of the working classes to support them; but even those most numerous and increasing in numbers, running the risk of abandonment at any time, become, with one or two exceptions, the expenses are greater than the receipts." Dr. Playfair is, in short, of opinion, from his experience as inspector of these schools, that the "system of self-support is not adapted to secondary schools of science, having only a constituency of working classes to support them."

Dr. Playfair has this to say of the connection with the Department, which appears to have been on the whole more successful. These are called Trade and Navigation Schools, and are intended to afford instruction to officers of the mercantile marine on the subjects of their examination at the Board of Trade. In the case of London, the Art School, located at Eastcheap, as a new experiment for the guidance of youth about to enter on a seafaring life. Besides these three in London, Trade and Navigation Schools have been opened in nine of the principal ports, and could be readily established in other shipping towns if the Department could train masters fast enough to meet the demand. One of these schools had "its present locality," when Dr. Playfair wrote, "somewhere in the ocean between England and India;" Mr. Green, of Poplar, having fitted out "one of his finest ships as a School of Navigation, carrying a number of the midshipmen under one of our [the Department] masters, who is bound also to instruct the common sailors in the principles of navigation." An example which might be well followed in this respect.

The Art Schools are of older date than the Schools of Science, and, appealing to a wider circle, have almost necessarily made greater numerical progress. The Art branch of the Department has, as we have already said, its head-quarters at South Kensington, on the estate purchased by the Commissioners of the Exhibition of 1851 [Exhibition of 1851. S. 2], and is a development or reorganisation of the old Schools of Design, whose history and constitution are given elsewhere. [Schoos or Dasso, S. 1]. As at present organised, Art Schools of Art consist of the Art sections of the Department, are, in the words of the official programme—"1. To train male and female teachers to give instruction in Art, to certify them when qualified, and to make them annual fixed payments, varying according to the examinations. 2. To aid and assist Committees in the provinces desirous of establishing Schools of Art. 3. To hold public inspections and examinations, and to award medals and prizes to the most deserving candidates. 4. To collect together works of art, pictures, &c., of the schools and book clubs established in the central Library. 5. To circulate among the Schools of Art objects from the Museum, and books and engravings from the Library."

The buildings at South Kensington include the offices of the Department, the Training School for Masters and Mistresses, the Normal Central School of Art, the Art Library, and the various Art collections.

The Training School has for its special object the education of Art-teachers of the class already mentioned, became in 1854 the property of the Government. The students have full access to the Museum and Library, either for consultation or copying, as well as to all the public lectures of the Department. Special classes are arranged in this School for master-masons and schoolmistresses of parochial and other schools to teach elementary drawing as a part of general education.

The collections brought together at South Kensington are already of great value and interest, and they are rapidly increasing. The Museum of Ornamental Art has been formed entirely by the Department. It was commenced in 1858, when a suite of rooms in Marlborough House was appropriated to this purpose. It was removed to the new buildings, South Kensington, in February, 1857. It embraces the entire circle of the arts, and is open to the public at a modest admission. The existence of majolica and other examples of ancient, as well as many most admirable specimens of modern, ceramic ware; a fine collection of old furniture of an artistic character; watches, jewellery, and enamels; stained glass windows; casts, engravings, and photographs of fine specimens of ornamental art from the Imperial Collections of France and elsewhere; casts of classical, medieval, and renaissance architectural ornaments, &c. There are also deposited in the Museum buildings, trade collection of animal productions, educational collections, models of patented inventions (deposited here by the Commissioners of Patents); a collection of original statues and casts by British artists, lent for a stated period by the sculptors or owners of the works, &c., to make the Department accessible to youth about to enter on a seafaring life. Besides these three in London, Trade and Navigation Schools have been opened in nine of the principal ports, and could be readily established in other shipping towns if the Department could train masters fast enough to meet the demand. One of these schools had "its present locality," when Dr. Playfair wrote, "somewhere in the ocean between England and India;" Mr. Green, of Poplar, having fitted out "one of his finest ships as a School of Navigation, carrying a number of the midshipmen under one of our [the Department] masters, who is bound also to instruct the common sailors in the principles of navigation." An example which might be well followed in this respect.

In connection with the Central School of Art there are seven Metropolitan District Schools, and one school for female students only. The provincial Schools of Art have increased greatly in number since the formation of the Department. These schools, combined with the Art sections of the Department, are, in the words of the official programme—"1. To train male and female teachers to give instruction in Art, to certify them when qualified, and to make them annual fixed payments, varying according to the examinations. 2. To aid and assist Committees in the provinces desirous of establishing Schools of Art. 3. To hold public inspections and examinations, and to award medals and prizes to the most deserving candidates. 4. To collect together works of art, pictures, &c., of the schools and book clubs established in the central Library. 5. To circulate among the Schools of Art objects from the Museum, and books and engravings from the Library."

The buildings at South Kensington include the offices of the Department, the Training School for Masters and Mistresses, the Normal Central School of Art, the Art Library, and the various Art collections.

drawing and painting to upwards of 35,000 students—but this number "includes children in poor schools under instruction in drawing," who can hardly in fairness be ranked as Art-students. The Department, in fact, now, besides the training which it affords in its central and metropolitan schools, and the Special Provincial Schools of Art in connection with it, proffers the services of a certified teacher in drawing to any school or schools, furnishing an aggregate of 500 children with a teacher for drawing; and is prepared to aid such schools of examinations and prizes, at stated periods. It is intended also, as soon as arrangements can be made, further to extend the aid of the central institution to local schools and provincial towns, through the招股 of objects of study set up in the Museum for exhibition and study upon application from the local authorities.

SCIRE FACIAS. A simpler, less expensive, and less dilatory method of proceeding than that by "cites facias," has been provided by the Common Law Procedure Acts, 1851 and 1853. The former statute has at the same time extended the period during which execution may issue, from a year and a day to six years. In case of a change by death, marriage, bankruptcy, or otherwise, in one of the parties to an action, the representative of that party may enter a suggestion of the fact, and put himself in his place. The opposite party is also enabled to call upon the representative to do so, and if he fails to stop the proceedings. The proceeding by suggestion on the rolls is adapted similarly to the parties. If it be not adopted, a writ of Review, as it is now called, may be issued, the object of which is the same as that of a "cites facias." It is however directed to the party and not to the sheriff, and is an action at law, not a suit in equity, and is directed to the sheriff of the county where the sense in the original action was laid, and was served by him. The subsequent proceedings in Review resemble those of an ordinary action. The writ of "cites facias" in Chancery to repeal patents is not affected by the above-mentioned statutes. Nor is the writ of "cites facias," itself abolished. In some cases it is still the only method of proceeding; for instance, to enforce a judgment against the terre ten sizes of a tenant in common.

SCILITIN. [Chemistry, S. 1]

SCITAMINACE., a natural order of plants embracing the Marantaceae, with 1 anther-valve, and the Zingiberaceae, with 2 anther-valves. The separation of these orders is now generally recognised. [Marantaceae; Zonoberaceae.]

SCOMBREDUSX., a genus of fishes belonging to the family Exocoj. The only British species of this genus is the far Pike or Skipper, called also Goodswin in Southland. It was first described as a British species by Ray. It is not often caught in the Thames, Berwick and Yarmouth, and Portland Island, and on some occasions has been even plentiful on the coasts of Scotland. [Exox.]

SCOPHELA., a family of Malacozygious Abdominal Fauna. They are closely shelled. They have the snout short, the mouth deeply cleft, the teeth rather small and sharp; the branchial rays 8 to 16; the first dorsal behind the ventral; the body in some is semitransparent. The genus Scopelus is found in the Mediterranean. (Manual of Natural History.)

SCORESBY, WILLIAM, was born in 1790, and commenced his nautical life only ten years afterwards, accompanying his father, William Scoresby, likewise a disting- guished navigator, in the Dundie, on her voyage of the year 1800. The passion for naval enterprise which the child's examination of the ship had evoked, was confirmed by his first voyage, and in 1803 the father and son sailed together in the ship Resolution of Whitsby. This they continued to do for the ensuing eight years, the sedulous junior keeping a regular journal of their voyages. He was promoted in succession, as he became qualified, without being unduly favoured, through all the gradations of the service, till he arrived at the command of one of the small 12' ships, which responsible office he held in his sixteenth year. The long intervals during which, from the nature of the whale-fishery, the ships were laid up in winter, were devoted by the father and son for the sanction and to the great satisfaction of his father, to researches into the organisation of various portions of two sessions, at Edinburgh, where he secured the friendship of the late Professor Jamieson and other professors of the university, and also of Dr. (now Sir David) Brewster. He thus acquired that definite knowledge of the principles of the various branches of science bearing upon his peculiar profession, which enabled him to extend them, by his own observations, in the voyages to the Arctic regions which alternated with and succeeded these periods of intellectual culture.

While filling the stations respectively of commander and chief-mate of the Resolution in 1806, the Scoresbys sailed to a higher latitude than had been reached before. In May of that year the ship bore down the eastern coast of Greenland, and in July left Spitsbergen at 70° 55' 20', inferior to that attained by the famous. ordinary sailing, and the honour still remains theirs of having in ordinary sailing navigated the highest northern latitudes. It may be remarked here that the boat expedition had itself been adopted from a suggestion made by the younger Scoresby (in a proposition which had been rejected by the Admiralty), but had not, in his opinion been properly executed. It was always his conviction that such an expedition, if carried out according to his views, the pole itself might have been arrived at; and in a later period he even favouring an object of learning that Party himself had expressed the same conviction. It is proper to note in this place, in order to preclude error, that the surgeon of the Resolution in this voyage, states, in an "Account of a Voyage amongst the Scoresby's," (now Scoresby,) in taking the achievement to himself, that the highest latitude attained was 81° 20', but this, as Dr. Scoresby has explained in his "Memoir of the Scoresby," p. 153, is erroneous; the highest latitude observed being 81° 12' 45', as already stated. The Resolution was the property of the late Sir Joseph Banks, President of the Royal Society, the attention of the council of that learned body and of the government was directed in 1817 to the dormant enterprise of endeavouring to reach the North Pole and discovering the long-sought North-West passage; the project was formed and applied for by Sir Robert MacClure in one of the recent searching expeditions for the ill-fated Franklin. Sir Joseph Banks was very desirous that his young but experienced friend should be engaged, and would not, in the face of his father having deferred the fitting out of the ship Falcon, the son to command, under the idea that she might be taken up for service. Their expectations however were altogether disappointed, and as is well known, Captain (the late Sir John) Ross with the Isabella and Alexander, Sir Captain Buchanan with the Dorothea and Trent, were appointed to make the attempt. It appears to be the policy, as perhaps to be recommended on grounds of national justice, however the consequences of it may be regretted in particular by the Board of Admiralty, to abandon all hazardous expeditions and others destined for marine scientific research, as the encouragement and rewards of an inevitably laborious and ill-paid service. The history of this subject will be found in a paper by Dr. Scoresby, "On some circumstances connected with the Original Suggestion of the Arctic Expeditions" published in the Edinburgh New Philosophical Journal, vol. xx. 1835-36.

Having made seventeen voyages to the Svalbard group of islands, and published a work in 1820, his celebrated work entitled, "An Account of the Arctic Regions, with a history and description of the Northern Whale-Fishery," in 2 volumes consisting of 1217 pages, illustrated by twenty-four engravings, it had been applied for a great service to scientific literature by stimulating his pupils and former pupils to make public the results of the observations made by them in their professional or official employment in distant countries. This was the first original work on the
physical and natural history of the countries within the Arctic circle and on the nature and practice of the Whale-fishery, published in this country, with the exception of a tract by Henry Elking on the latter subject. It obtained for the author a more general reputation than he had hitherto enjoyed. The Mental Philosophy of the Whale-fishery, commanded, in counteracting a degree of enterprise in geographical discovery—not connected however with the object of the trade—which had not before been united with the pursuit of whales, except through accidental circumstance, was the result of a voyage in whaling from a voyage in 1828, in the ship Baffin of that port, undertaken with these views, he received on entering the Mersey the afflicting intelligence of the decease of his (second) wife while he was absent. He now quitted the whale-fishery, but published the geographical and scientific results of his voyage, in a 'Journal of a Voyage to the Northern Whale-fishery; including researches and discoveries on the eastern coast of West-Greenland, made in the summer of 1829, in the ship Baffin of Liverpool,' Edinburgh, 1830, 615 pages, with 6 plates, including a chart, &c. A German translation by Professor F. Kries was published at Hamburg in 1835. Not long after the appearance of this work, on the 17th of June, 1834, he was elected a Fellow of the Royal Society, being also a member of the Philosophical Society of Manchester, and having been for some years a Fellow of the Royal Society of Edinburgh. He subsequently received one of the highest honorary rewards of scientific eminence, in being made a corresponding member of the Institute of France, or Académie des Sciences; and various questions were always presented to him he had been a remarkable man. His crews were always distinguished by their discipline and respectability, and the lasting effect of his command upon the characters of some of those who sailed with him was a proof of the soundness of his management. The whale-fishery was remarkable; but he never, under any circumstances, allowed a whale to be pursued upon Sunday, and he succeeded in convincing his men that upon the whole they did not lose by keeping the appointed day of rest. In 1836, he was one of the temperance principal on board his vessel, finding that hot coffee was a very much stronger preservative than spirits against the intense cold of Arctic regions.

Some years after his retirement from the whale-fishing the religious impressions which he had first received from his father and had always entertained, impelled him to desire a more formal and authorised position as a teacher of religion. He entered the University of Cambridge as a student of Queens' College, and in 1839 proceeded to the Master of Arts. Orders in due course, taking the superior degree of D.D. in process of time. The Mariner's Church at Liverpool having then been just established, he accepted the chaplaincy. Private circumstances occasioned his removal to Exeter, but the zeal with which he discharged the duties of his office in Yorkshire, after some years he however resigned this office, and retired to Torquay in Devonshire.

As a clergyman, Dr. Scoresby is stated to have "combined what may perhaps be considered extreme vantages with the most abounding charity and liberality to those who differed from him." His 'Discourses to Seamen' evince the earnestness with which he laboured for the good of the sea in which he had passed his earlier years. He took also enlightened and enlarged views of public education, which while vicear of Bradford he laboured zealously to realise. But of all the very various subjects to which Dr. Scoresby directed his attention, practical magnetism and its relation to navigation appear to have been most actively pursued by him during his life. The increasing quantity of iron introduced into the equipment and construction of ships, and the recent construction of the entire hull of that metal, were watched by him with increasing care; and all the resources of his cultivated mind were at length applied to the most important of all the great subjects of the science of navigation. His researches into the properties of ships upon their compasses, and the requisite correction of the indications of the latter. He had published various papers on magnetism in the 'Philosophical Transactions,' the 'Society of Arts' Reports of the British Association,' the 'Edinburgh Philosophical Journal,' and the two journals which succeeded it. The substance of these, or of many of them, he now made public, in an improved form, in his 'Magnetical Investigations,' Part I. Comprising investigations on the principles affecting the capacity and retentiveness of steel for the magnetic condition; with the development of processes for determining the quality and degree of hardness of steel. London, 1839; 292 pages, 2 plates. Part ii. 'Comprising investigations concerning the laws or principles affecting the power of magnetic steel-plates or bars in combination, as well as singly, under various conditions as to mass, hardness, quality, form, &c., together with some interesting facts respecting cast-iron.' London, 1843; 290 pages, 2 plates. Vol. ii, part iii, 'Investigations, with illustrative experiments, on the nature and phenomena of magnetic induction, and the mutual influence of magnetic bodies. London, 1852; 480 pages. To the section of Mathematics and Physics, at the Opening of the British Association at Glasgow in 1855, he communicated a summary of his matured views, and of the evidence in their favour which had occurred since their original presentation. 'Investigations, Principally on the Magnetism of Iron ships and its changes.' In this he recalled attention to his plan of a compass alaft, as affording a simple and effective mode of ascertaining the direction of a ship's course, stating that it had not only been extensively adopted by some of our first friends in the building and property of iron ships, but had received the particular sanction and commendation of Mr. Airy, the astronomer, and of Lieutenant M. F. Manly, the American hydrographer, who had recommended it by both these gentlemen for adoption for determining the position of the vessel, or the correction of adjusted compasses whenever they might be found to be in error. In the further prosecution of his researches on this subject, and with the view to determine the specific magnetic quality of iron, he made a voyage in his ship at the Austral in 1857, and at the 21st of March 1857, aged sixty-seven, and leaving a widow.

Three principal scientific works of Dr. Scoresby have been described above. The following enumeration will render the account of his separate publications nearly complete. 'Memorial of an Aërotectic and Dutiful Son, Frederic R. H. S., who fell asleep in Jesus, December 31, 1834, aged 16 years.'—Discourses to Seamen: consisting of Fifteen Sermons, preached in the Mariner's Church, Liverpool, for the most part generally on subjects of Christian Practice and Doctrine. "—Isowlad glorified in his Works: a Memorial of a Merciful Instructor, and a Loyal Servant of his Country. August 4, 1850, on occasion of the Meeting of the British Association."—Memorials of the Sea ': 1, 'Sabaths in the Arctic Regions'; 2, 'The Mary Russell.' Of both these editions have appeared. 3, 'My Father: being Records of a Life of Robert H. Scoresby, 1807-1877.' Whitby, 12mo, Lond., 1851, pp. viii. and 322. 4, 'The Franklin Expedition,' stating his views on its probable course and fate, and on the measures for search for it. "—Polar Researches; or, the Natural History of Plants belonging to the natural order Asteraceae. The pappus is feathery, in several rows. Brist's imbricated. Reception naked. Achenia neither stalked nor beaked, with a lateral scar. S. Hapsonia, Viper's-Grass, has a cylindrical succulent root, branched monopodically leaves annual, lanceolate, wide, involucres smooth; flowers yellow. It is found

K 2

4
in Spain and the south of Europe. The root is said to be
and eatable, and is supposed to be
a specific against viper bites.

*G. saltifolia* has roots similar in quality.

*G. dulcis* is cultivated as an esculent at Palermo, and the
gummy root of *G. tenuifolium* is eaten by the Kalmucks.

SCOTOPHILUS. [Chiroptera.]

SCOTT, DAVID, was born in Edinburgh, October 10, 1806. The son of a landscape engraver, he was brought up to the
trade by his father, but he was sketched and drawn incessantly, and at length his father yielded to his desire to become a painter. From this early ambition he was skilful in the 'grand style.' His early pictures were of subjects such as the *Hopes of Early Genius and the Spirit of Loli,* and of *Lot and his Daughters flying from the Cities of the Plain.* Of a melancholy turn of mind, and of somewhat gloomy theological views, his pictures naturally were a sombre air, and attracted few admirers beyond the circle of his friends. His *Lot and his Daughters* was returned from the British Institution as too large; his series of outline etchings, *Monograms of Man,* met with a slow and unremunerative sale; and it was not till 1831 that he sold his first picture. But he loved labour, and he went on painting subjects with which few could sympathise, in a manner that did little to remove the unattractiveness of the theme. Slowly however he made his way, finding ardent if not numerous admirers; and he was now privileged, be it to his fellow-citizens. In 1832 he visited Italy, staying awhile at the Louvre on his way. In Italy of course his chief stay was at Rome, but the amenities of Raffaele seem rather to have repelled him, his chief attention, characteristically enough, being directed to the engraving of the façade of St. Peter's, to the acquisition of the leading resident artists; he worked hard, and painted much; and his power in painting was evidently enlarged. His style however was not materially changed. He continued to paint in the 'grand style' pictures of heroic size; and even when he stooped to the simpler realities of life, or to such matters as 'Love whetting his Darts,' *Ariel listening to the Mermaid,* 'Beauty wounded by Love,' the *Triumph of Love,* and the like, it was not the use of as an object of an altogether different character. In the acquaintance of his themes he entered upon with more congenial feeling were such as his *Genius of Discord* (a large work, painted at Rome, but repainted on his return); *Descent from the Cross,* *Jane Shore found Dead in the Street,* *Orestes pursed by Furies,* *Achilles mourning over the Dead Body of Patroclus,* *Paracelus, the Alchemist,* in his Lecture-Room; *Hope passing over the Horizon of Despair,* *The Dead rising at the Crucifixion,* *Peter the Hermit addressing the Crusaders,* and several others, which all attest his remarkable diligence and his soaring ambition; but which, in their want of power to interest the spectator, and their artistic shortcomings, too clearly show that lofty ambition, strong imagination, and unwearied industry, are insufficient to give a purpose, even when a well-directed purpose, and carefully disciplined technical skill. Mr. Scott had built himself a large studio in Edinburgh, and was full of dreams of future glory, despite the warnings of failing health, when the cartoon competition in connection with the new houses of parliament aroused his feelings to a high pitch of excitement. He prepared and sent in a large cartoon of *The Defeat of the Spanish Armadas* upon which admired the judges who awarded the prizes, and the block upon which the cartoon was taken, of similar in its intensity to that which the like fate inflicted upon Hayden—whom in his ambitious thoughts, and passion for grand art and huge canvases, Scott greatly resembled. But Scott had died; he devoted now all his energies to his largest and perhaps, on the whole, best work, *Vasco da Gama encountered by the Spirit of the Storm in passing the Cape,* now in the hall of the Trinity House, Leith. This work occupied him during the last ten years of his life, and he lived only to complete it. In 1840, he was forty-third year. Some of his great works have been purchased for public institutions in Edinburgh. Scott was a vigorous writer both in prose and verse. His *Essays on the Character of the Best Masters* excited a good deal of attention when first published in 'Blackwood's Magazine,' 1840; and some of his poetry is contained in the *Memoir of David Scott, R.S.A.,* containing his Journal in Italy, Notes on Art and the Theatre,* Svo, 1860. This *Memoir* is a warm-hearted tribute to his worth and merits by his brother, Mr. William B. Scott, himself an artist of considerable ability.

SEBASTIANI, HORACE FRANCOIS, COUNT, was a native of Corsica, having been born at the hamlet of Porto, near Bastia, on Nov. 11, 1776. His uncle, who was a priest, took charge of his education, and was preparing him for his own profession, when the call to arms, in 1792, induced him to resign. He then became engineer for General Casabianca, after which he joined the army of Italy, in 1796, was noticed by Bonaparte, and we made a chef-de-bataillon at the battle of Arcola. In 1796 he distinguished himself greatly at Verona, for which conduct he was appointed to a regiment on the field of battle. On the 16th Brumaire, being in garrison at Paris, with his regiment of Dragoons, he assisted in the coup d'état by which Bonaparte became master of France. The First Consul promptly rewarded this proof of devotedness on the part of his comrade, and henceforth took charge of his fortune.

After the battle of Marengo (June 14th, 1800) Colonel Sebastiani was appointed commissioner along with Marcetot of the Russian prisoners of war, a post that brilliant corps entered the Austrian capital. At the battle of Austerlitz he displayed his habitual energy, was badly wounded in a desperate charge, and was raised to a division for his conduct. During the next few years he was employed with much distinction in directing his division against the Russian army, and was killed, his wife, who died in giving birth to a girl, afterwards known as the unfortunate Duchesse de Praslin, murdered by her husband in 1847.

General Sebastiani was one of the many French officers sent to Spain to retrieve the fortunes of the Emperor, in 1809. He crossed the Guadarrama, and defeated the Spanish at Ciudad-Real, at Santa Cruz, and several other places. In the early part of 1810 he took possession of the provinces of Aragons, Murz, and Majorca, and he accused of having greatly mutilated the Alhambra and other monuments of antiquity, and of ransacking the convents for his own private gain. In the following year, not deeming his services sufficiently appreciated, he returned to France. Napoleon I, who considered the chief talents of this general to be diplomatic rather than military, had determined not to give him a command during the Russian campaign. But the remonstrance of Sebastiani overcame this decision; he was therefore sent to the Russian army. During the march to Moscow he strongly urged upon the Emperor the prudence of wintering in the province of Littuania; but this advice was unheeded. General Sebastiani was present at all the battles of Smolensk and Moscow; he held the post of the first to enter the Russian capital, at the head of the Red corps. He suffered greatly during the retreat, lost all his artillery, and all his horses perished in the snow.

In 1810, after the battle of Leipzig, at which he was wounded, he contributed to the victory at Hanau, when...
Prince Wrede was defeated. Napoleon afterwards gave him the command of the 5th corps, and ordered him to defend the left bank of the Rhine, at Cologne; but he was obliged to fall back into Champagne, where, at the head of three regiments of cavalry of the Imperial Guard, he repeatedly won new honours, particularly at the battles of Arcis-sur-Aube and Saint-Dizier.

On the retirement of Napoleon he retired to private life, but during the Hundred Days he became a member of the Chamber of Representatives, and was sent as one of the deputies to wait on the allied sovereigns after the battle of Waterloo. After the return of the Bourbons he spent a few months in Paris, afterwards resided in the country, and when he included his name in their list of subscription. In 1819 he was chosen deputy for Corsica, and soon became distinguished as a member of what was termed the liberal opposition in the Chamber of Deputies. In 1820 he succeeded General Foy as representative of the 1st section of Paris. After the revolution of 1830, Louis Philippe, in August, appointed him minister of marine, and in the following November, on the retirement of Molé, made him minister for foreign affairs, in which office he continued until 1832. It was during his administration of this office, in September, 1831, that he incurred so much obloquy by his famous announcement from the tribune of the chamber that "order reigns in Warsaw." In 1833 he was appointed consul for a short time the office of minister for foreign affairs, and on his return to Paris had a difficult task to confirm the treaty he had made with the United States of America, and was appointed ambassador to Naples. In 1835 he was sent ambassador to London, where he was replaced by the Duke of Angoulême, who in a few months received his bâton de Maréchal after 45 years service. In 1841 he spoke strongly in the chamber in favour of the project for fortifying Paris. Ill health compelled him soon afterwards to retire from public business, and the unfortunate fate of his daughter, the Duchesse de Praslin, darkened the latter years of his life. He died however suddenly while at breakfast, on July 20, 1851. He was buried in the church of the Invalides, and during the funeral some of the hangings caught fire, and the building, but the fire was fortunately subdued with only the loss of several of the military trophies.

SEBASTEN PLUMS. [Conrad, S. 2; Cordiaae.]

SECALE, a genus of Grasses, to which the cultivated Rye belongs. The flowers are arranged on a spike; the spikelets are 2-flowered, with a long stalked rudiment of a third floret; the glumes are subulate. In other respects this genus strongly resembles Tribicum, to which the Common Wheat belongs. [Triticaceae.]

S. cereale, Rye, has the glumes 1-nerved and shorter than the spikelet; the rachis is very tough. This plant is extensively cultivated in Europe, and nowhere has been observed in a truly wild state, away from the possibility of escape from the field. It is deciduous in winter. [Ryce.]

S. montanum has the rachis hairy, brittle; glumes with a short point; the root fibrous. It is found on the gravelly mountains of Sicily.

S. milletus is also a European species, in which the spikelets are 4-flowered, and the glumes have 2 or 3 strong ribs. It is found in France.

SECRETIONS OF PLANTS. [SECRETIONS, VEGETABLE.]

Although the term secretion is generally connected with the idea of separating for the purpose of throwing off or getting rid of a product, it is very manifest that such a use of the term would restrict its application to the substances which, amongst animals, are called excretions. It does not appear that the term is in use in a more restricted sense than another in the vegetable kingdom. It is true that a theory of the practice of 'rotation of crops' supposes it to depend on poisonous excretions given off by the roots of one plant which are not poisonous to another. But the facts brought forward to support this theory are doubtful, and other explanations of the necessity of rotation have been given. [Root.]

In plants the organs of secretion are simpler than those of animals, as they have no specialized ducts for carrying the secretions as the blood. This function, however, seems to be performed in both plants and animals on the same general plan. It is in both cases in the interior of the cell that the most remarkable instance of the process takes place. For this reason the terms 'plant' and 'animal' are frequently used in植物 physiology. The chemical forces in action during secretion are stronger than in animals. All the important secretions of plants are compounds of the four organic elements: carbon, hydrogen, oxygen, and nitrogen. These enter the plant in the form of carbonic acid and ammonia. Out of these compounds the various substances are formed. The principal of the wood of plants, the nutritious value to their seeds, roots, and other parts, the colour and scent of their leaves and flowers, with the medicinal virtues of many special plants, are formed. The substances secreted are generally distinguishable, and may be divided into two great classes.

First, Nutritive or Assimilable Secretions, that is, substances which have been formed in the plant, and are used for forming its tissues, and constructing the mass of which it is composed. The principal of the wood of plants, the nutritious value to their seeds, roots, and other parts, the colour and scent of their leaves and flowers, with the medicinal virtues of many special plants, are formed. The substances secreted are generally distinguishable, and may be divided into two great classes.

The second class of substances are called Non-Assimilable or Special Secretions of Plants. They are substances which are not found in every part of every plant. When once formed are never recorded in the stock of the plant, and are never converted into the nutritive secretions; hence they are called non-assimilable. Some of these substances are very generally diffused amongst plants, as chlorophyll, which is found in all the green plants; others which give the peculiar green to the leaves and other parts of plants. [COLORFULITY, in Fig. 1.]

These secretions are very numerous, and may be classed under certain general heads.

1. Colorant. To this head may be referred chlorophyll; the colouring principle of the petals of plants seems also to be a modification of this substance. There are however other colouring matters in plants, such as those used by the dyer, and which do not give any colour to the plants in which they exist, which have nevertheless a very definite chemical composition, and by combining with various other substances produce the colours used by the manufacturers of coloured cotton, linen, silk, and woollen cloths of various colours. Various substances are termed dyers' stuff, from the decomposition of the assimilable secretions, as many of them bear a close relationship to both the ternary and quaternary forms of these secretions.

2. Acid. Plants which having an acid reaction, and capable of combining with the oxides of the metals, are very common in the vegetable kingdom. The most familiar are those which occur in fruits, as the oxalic, citric, mellow, and tartaric acids. Oxalic acid is found in the Oxalis Acetosella, hence its name, and other forms of Oxalaceae. It is also found in the Cactaceae and Polygonaceae. In the latter order it exists in the species of Rhamnus (Rubarb), used for making pies, and also in the Sorrel (Rumex). In all these cases it is combined with the oxide of some metal, either potassium or calcium. In sorrel (Rumex acetosella) it exists as a quinon-ol or superoxide of potassa, which, when separated, is called Salts of Sorrel. In the Cactaceae it exists as an insoluble oxalate of lime, in the form of raphides. These substances are very common in the vegetable kingdom. Citric Acid is found in the fruits of the order Aurantiosae, as the lemon, orange, lime, shaddock, &c. It is easily separated from these fruits in a crystalline form. It is soluble in all its combinations with the oxides of the metals, hence it does not occur as oxalic acid in the form of raphides. Tartaric Acid is found in the juice of the grape. Though closely resembling citric acid, it differs in forming an insoluble compound with potassa. Various substances that give the peculiar green to the wood of the tartar of the shops. This salt is deposited whenever grape-juice is allowed to stand. It forms the basis of the tartar of wine procured from the lees. This property of tartaric acid makes the juice of the grape the most efficient compound for the manufacture of wine. This is tasted in the formulation of citric acid, whose salts are soluble, are much less suited for wine-making. Malic Acid is the acid found in the apple,
and which gives the sour taste to verjusce, as also to the fermented juices of the apple and pear—cider and perry. The chemist has discovered that there is a very large number of organic acids as present in plants, and every day is increasing their number. Many of the colouring matters appear to be acids, which assume their particular colours by combination with metallic oxides, such as the lactic, orvallic, ethyrlic, and parele acids, obtained from lemons, used in making curd cheese and archil. The vegetable alkali's, or alkalois, are also found in combination with acids; thus, ascorine is found in combination with acetic acid, morphia with meconic acid, and a variety of others.

The acids generally occur in combination, and sometimes supplant each other. Even mineral acids will sometimes take the place of organic acids; thus sulphuric acid is sometimes found combined with morphia in the place of meconic acid. On the other hand, the metallic oxides will sometimes take the place of the alkalois, and be found in combination with the organic acid. In the instance however of gallic and tannic acids, there appears to be no combination with alkali's or alkalois. Tannic acid, formerly called tannine, is found very generally present in most woody parts of plants. They are supposed to result from the decomposition of cellulose. Theoretically, it may easily be formed out of carbonic acid and water. Whether it passes through the stage of cellulose is doubtful. It is of great use in the arts, especially in tanning leather, and for these purposes it is obtained from the bark of elm, oak, willow, sumach, and other trees. It exists in the fruits of the Carya, and the legumes which are called 'divi divi.' The vegetable extracts called catechu, or cutch, and the exudations which are sold by the name of kols, are all composed of tannic acid. This acid is converted into gallic acid by oxidation. Such a process takes place during the formation of the galls produced by the puncture of insects in the buds of many of the species of oak, and the hornbeam.

These excrencences are called gall nuts, and from the presence of this acid in them it has been called gallic acid. [Gall.] The alkaloids are substances found in the leaves, fruits, bark, and other parts of plants. They are some of them organic, others mineral; but most of them are of the latter class, and more generally diffused. Many of them possess extraordinary properties in relation to the animal kingdom, producing poisonous effects: such as strychnia, from the Strychnos Nux vomicae; morphia, from the Papaver somniferum; quinina, from the Coixs matthiali. These substances are always found in combination or organic or mineral acids. There is however another class of substances closely resembling these in their composition and action, which do not contain metallic oxide, and which are called organic substances: such as theine, the principle found in tea, coffee, and Paraquay; and theobromine, the principle of cocoa. The volatile oils are another group of secretions of great interest. They differ in composition and character from the mineral acids, and are not susceptible of the same action by secretions. They are many of them used as perfumes—others as stimulant medicines, and are remarkable for the interesting compounds they can be broken up into by the agency of chemistry. Their investigation is throwing much light on vegetable chemistry. [Oils.]

The resins are a group of substances standing in a similar relation to the fixed oils, as the volatile oils. They do not appear to be assimilable, they are only occasionally formed, and present special properties in particular plants. They are generally composed with gum, forming the substances called gum-resins, and from this combination it may be supposed that they are directly formed from the tertiary assimilable secretions. When occurring with gum, as in the case of the gum-resins of the Umbelliferae, or without gum, as in the resins of the Coniferae and in Myrrh, they are combined with volatile oils, which appears to give them their peculiar odours, mavour, and action. In the Coniferae the volatile oil they are combined with is the same in most species, and is in fact none other than the same type of oil with which, we are at present acquainted, we can readily explain their formation from the carbonic acid, water, and ammonia, taken up by plants, and the loss of oxygen. The following tables illustrate this process, with regard to several of the substances mentioned:—

It should not however be lost sight of that other elements besides the four organic are constantly found present in the secretions of plants, such as paraffin, and phomium, from the leaves, grasses and albellums. The alkales and alkaline earths are found very commonly associated with all these secretions, and it is very certain that plants will not form their secretions unless the inorganic elements are present. [Chem. of Plants:]

**SEDE, SEDES. [Claudium, S. 1; Cypræacum.]**

**SEDGELEY. [Staffordshire.]**

**SEINE-MARITIME, a department in France, recently constituted with Havre for its chief town, extends along the coast of the English channel from the Seine to the Bresle. It is formed out of the coast portion of Seine-Inférieure, which bounds it on the south. The Bresle separates it from the department of Somme. It is divided into five arrondissements, Havre, Le Havre, Yvetot, Dieppe, and Fecamp. Goury, a small coast village, east of Trouport, are made chief towns of cantons. The tribunal of commerce of St.-Valery is suppressed, and that of Yvetot transferred to the more important town of Bolbec. A change has also been made in the limits of Seine-Inférieure, to that portion of the territory of the department of Eure that lies east of the Seine to the Epte is added. Seine-Inférieure, by this arrangement, has Seine-et-Oise to the south-east; and out of the new territory two new arrondissements, Eilbaupt and Goury, are chiefly formed. At Goury, the railways authorised to be made from Amiens to Rosen, and from Bernay to Trouport, through Annule, are to meet. In the absence of any official return, it is useless to offer any conjectures on the number of the new department; though these may be very nearly ascertained by consulting the articles Eure and Seine-Inférieure, which have been described as they stood previous to the recent alterations.

BENEQUINE. [CHEMISTRY, S. & T.]
SEPARATE PROPERTY. The savings and earnings of a wife may become her separate property at law; and she may deal therewith as a feme sole, either where an order has been made to that effect under the statutes 30 & 31 Vict. c. 55, or a judicial separation has been obtained by the wife. [Divorce, S. & T.; Justice of the Peace, S. & T.]

SEPARATION, JUDICIAL. Until the statute 20 & 21 Vict. c. 65, divorces a vinculo, which put an end to the marriage altogether, were only obtainable by a special Act of Parliament. The system has been adopted by men who have a husband, until after a sentence of separation a mensa et thoro in the ecclesiastical court, and would not pass at all if his conduct had not been free from reproach. [Divorces.] Either of the spouses could always however obtain on the ground of adultery, cruelty, and certain other causes, a divorce a mensa et thoro.

The remedy now given in such cases by the Court for Divorce and Matrimonial Causes is termed a judicial separation. The divorce a mensa et thoro does not dissolve the marriage; it does not bar the wife of her dowry, for instance; it effects only such a separation of the parties as leaves it open to them to come together again. But it relieves the husband from all liability for his wife; and it comes into play only in cases where the parties having and disposing of her own property and earnings, as freely as if she were a feme sole.

This kind of separation may be obtained on the ground of adultery or cruelty, or desertion without cause for two years or upwards, but unlike a decree for a divorce a vinculo is always possible. The less of judicial separation may be reversed at any time afterwards, if obtained in the absence of the defendant, on its appearing that there was reasonable ground for the alleged desertion.

In cases either of divorce or judicial separation, the Court may, if it shall think fit, order that the husband shall secure to the wife such sum as it shall deem reasonable. The allowance which may thus be made to a woman for her support out of the husband's estate, is to be settled at the discretion of the court, having regard to the probable future means of each of the parties, and to be proportioned to the rank of the parties. [Divorces, SIR ROBERT, F.R.S., the distinguished naval architect, received his education as a shipwright under Sir John Heath, surveyor of the navy, and continued in the service with the important service of our dock-yards during a period of fifty years. He was the author of many improvements in the first order in our naval architecture, including the system of diagonal bracing, which was devised while he was master shipwright of Chatham Dockyard. This system formed the subject of two memorable papers in the 'Philosophical Transactions' of the Royal Society, for the years 1814 and 1816, one by Sir R. Seppings in each of those years, and one by Dr. Thomas] in the former, and which attracted an unusual amount of public attention. The great principle of this method was such an arrangement of the principal timbers as was designed to check the tendency of the ribs and other timbers in every part of the ship, thus firmly compacting together the entire fabric, and preventing that perpetual racking of beams and working of joints which in the ancient system of ship-building, produced hogging, cracking, leakage, and rapid decay; and filling up likewise every vacancy between the timbers, which are occasionally the unavoidable receptacles for foul air, filth, vermin, and various other sources of rottenness and disease. These important improvements, though opposed to the ineradicable prejudice of the old system, were gradually adopted, but not sufficiently valued and understood, in this country at least, the just principles of mechanical action, in the practical operation of ship-building, were universally adopted in the maritime countries of the North Sea, especially that of Mr. Charles York, and the powerful advocacy of Sir John Barrow in the 'Quarterly Review,' and the merit of their author was acknowledged by his appointment as surveyor of the navy, and by the award of the Copley Medal of the Royal Society, which he became a Fellow on the 10th of November, 1814.

While the claims of Sir R. Seppings to the invention of the system of diagonal bracing in naval architecture is indisputable, it may not be out of place to record here the following point of information. It can be made a demonstration of the merits of discoverers or inventors to show that their progress in a portion of the general advance of the human mind. Sir John F. W. Herschel has stated in a letter to Mr. G. R. Weld, Associate, R.C.S., inserted in the 'History of the Royal Society' by the latter, that he is "disposed to think that the system of triangular arrangement adopted by Sir W. Herschel in the wood-work of his great telescope, being a perfect system of diagonal bracing, or diagonal approach, was independently invented by the "diagonal bracing," which system owes its strength, was original with his father at the time of its construction, that is about the year 1766.

Sir Robert Seppings introduced other improvements into the science of naval architecture. The admiral of the fleet presented him with 10,000 as a reward for his simple yet most useful invention of an improved block for supporting vessels, by which their keels and lower timbers were much more easily adjusted and prolonged or repaired. It was produced while he filled the office of master-shipwright assistant in Plymouth dockyard, and is described in the 'Transactions of the Society of Arts' vol. xxii. p. 275-252, the Society having awarded him their gold medal for it in the year 1804. His plan for lifting masts out of the steps, which superseded the employment of sheers hulk for that purpose, has been the means of saving much expense and labour. His new mode of framing ships has led to a much more extensive use of short and small timbers, which were formerly of little value; but the most important of all his improvements in the system of building ships. Sir Robert Seppings having been made a fellow of the Royal Society, in 1817, he was presented by his students with the sum of 500, and a plaque, on which was engraved his portrait, in addition to his official emoluments, and he received the marked approbation of both houses of parliament.

Foreign nations were not tardy in acknowledging the value of the improvements in ship-building originated by Sir R. Seppings, and his author received many substantial proofs of their sense of his merits; the Emperor of Austria, and the kings of Denmark and Holland, presented him with memorials of their appreciation of what he had done for their respective navies. He died in his 82d year; was buried in the national record of the great benefactors of their country, there are few names which will deserve more grateful commemoration than that of the object of this notice. In addition to the papers on the diagonal bracing already alluded to, Sir R. Seppings presented the Society with a sketch of a scheme of constructing ships in the mercantile navy, which was inserted in the 'Philosophical Transactions,' for 1820. Dr. Young's paper, also referred to above, though not communicated to the Royal Society, in 1814, had been presented in the form of a report to the Board of Admiralty in 1811. It will be found reprinted in Dr. Peacock's edition of the 'Miscellaneous Works' of Young, (vol. i. p. 562-568) together with the official correspondence relative to it between the latter and Sir J. Barrow. Sir R. Seppings was an honorary member of the Cambridge University Philosophical Society, and a corresponding member of the Philosophical Society of Rotterdam. It had been proposed by the University of Oxford to confer upon him the honorary degree of D.C.L., at the commencement of the ensuing year, but the health of Sir R. Seppings failed him to decline it. He died at his house at Taunton in Somersetshire, on the 20th of April 1840, aged seventy-two, leaving several children; his wife's decession had taken place a few years before.

BERICA. [MELOLITHOM.] SERICOSTOMA. [PHLOIPEN]. SERICULUS. [MERULIDE].

SERPENTINE. As a mineral Serpentine occurs, although rarely, in the UK, being a fairly fine-grained mineral and compact in texture, and of a dark-green or blackish-green colour. It also occurs in fibrous and lamellar varieties. Its hardness is 2.5 to 4, and it may be cut with a knife. Its specific gravity is 2.5 to 2.6, it becomes yellowish-gray on exposure, and feels sometimes a little mucous. The following varieties are recognised:—

Precious Serpentine.—Purer specimens of a rich oil-green
colour, and transmittant, breaking with a splintery fracture. It is a red-brown stone when polished. It has the following composition—

<table>

**Picrolite, Schiller Asbestos.**—A Fibrous Serpentine, of an olive-green colour, containing asbestos in Serpentine. The fibres are long, fine, and brittle. It resembles some forms of asbestos, but differs in its difficult facility. Thomson's *Balkotine* belongs here.

**Marmolite.**—A Foliated Serpentine, of greenish-white and light green-shades of colour, and pearly lustre, consisting of thin folia rather easily separable. The folia are brittle, and the variety is thus distinguished from talc and brucite. It has the following composition—

<table>

</tbody>
</table>

**Kerolite.**—Near Marmolite, but not separable.

**Serpentina** is a very handsome stone, when polished. Beautiful specimens from Cornwall, and other parts of England and Ireland, may be seen in the Museum of Economic Geology, London. When mixed with limestone it constitutes the Verd-Antique Marble. It does not wear well, although at first it receives a fine polish. Chalcedony iron is usually found disseminated through it. Dr. Jackson of America has shown that Epsom salts or sulphate of magnesia may be profitably manufactured from Serpentine.

**SERRATULA.** a genus of Compositae, Plants of the order Cynaraeae, and the section Serratulae. The heads of flowers are discoid by abortion; the involucres are imbricated, sharp, and unwedged; the scales of the receptacle split longitudinally into linear bristles; fruit compressed, not beaked; balsam areoles oblique; the pappus persistent. There is but one British species of this genus, S. tinctoria, the Saw-Wort. (Babington, *Manual of British Botany*)

**SERVIA or SERBIA,** a political division recently formed by decree of the emperor of Austria, consisting of portions of South Hungary and Slavonia. It is styled the Woidow- 
schaft of Servia and Tesembar Banat, and includes the Banat of Tesemvar (comprising the counties of Bac, Bodrog, Temez, and Kruse), to which several other words, the territories of the Bacza and the Banat), and the Syrmian districts of Unca and Ilok. The emperor is styled Grand-Woidowe, and the actual governor Vice-Woidowe, who resides by a ministerial commission and a native administrative council. The woido-
schaft is divided into 6 districts. It has an area of 11,538 square miles, drained by the Maros, the Temez, the Theiss, and the Danube. The population amounts to 1,426,211 Serbs, Wallachs, Germans, and Hungarians. [Croatia; Hungary; Tesemvar.]

**SERVITUDE, PENAL.** This punishment has come in
place of the former punishment by transportation, said to have
existed in the Roman law c. 358. a. C. The first Act
by Parliament on this subject is the 15 Car. ii. c. 3, 5, 8,
enabling the judge of assize to transport certain offenders to
America, there to remain and not to return.

§ 29 Car. ii. c. 5, 8, 4 gave the judges power, "at their discretion," to grant a reprieve, and to cause felons to be transported beyond the seas, there to remain for the space of seven years; but if the offender refused to be transported, or returned within the time, then he was to be put to execution. The 32 Car. ii. c. 5 directed a judgment of transportation in default of the felon elected to be transported, and it authorised the sheriffs to cause offenders to be embarked. It also made a return before the expiration of the sentence, a capital felony. The next statute is the 20 Car. ii. c. 11 "for the foundation of the law of transportation," which enacted that when the Crown should be pleased to extend mercy, upon condition of transportation to any part of America, any court, having proper authority to do so, might direct the offender to be transported "at large" in Great Britain, before the expiration of the term of transportation, liable, on conviction, to suffer death. The 8 Geo. iii. c. 16, extended the powers of the judges to make orders for transportation by enabling them to do so as judges of assize, by the sentence of death. And in c. 47, the king was empowered to authorise the governors of convict settlements to remit the sentences of transports.

By the 5 Geo. iv. c. 84 (amended by 11 Geo. iv. c. 1 and Will. iv. c. 30), consolidating the laws on the subject of transportation, enabling in some cases to remit the places beyond the seas, to which persons under sentence of transportation should be conveyed, the governor or other person to whom they were delivered, or his assignee, was authorised to substitute for their service any person of their own choosing. The title was also empowered by warrant to appoint places of confinement at home, either on land or on board vessels in the Thames, or other rivers or harbours, for the confinement of male offenders (recently extended by the 16 & 17 Vict. to females) under sentence of death, but reprieved or respited, or under sentence of transportation, to remain there under order of the secretary of state until entitled to their liberty, or removed, or otherwise dealt with. The capital punishment for offenders found guilty, was also abolished by the 5 Geo. iv. c. 67, which substituted transportation for life, with previous imprisonment not exceeding four years.

New South Wales, Van Diemen's Land, and Norfolk Island, thus became the principal receptacles for convicts. Although the property in the services of these persons was vested in the colonial governor or his assigns, a practice prevailed of granting them, in certain cases and on certain conditions, permission to employ them for their own benefit. These permissions were usually called "tickets of leave." By the 6 & 7 Vict. c. 7, the legislature, thinking it just, that ticket-of-leave convicts should be protected in their persons, and in the possession of such property as they might acquire by their industry, empowered them to hold personal property, and to maintain actions in respect thereof while such tickets remained unrevoked.

The reception of convicts having, however, become distasteful to the inhabitants of the colonies, the stat. 10 & 11 Vict. c. 67, was passed, permitting offenders under sentence of transportation to be removed to any prison or penitentiary in Great Britain; directors of the principal convict prisons being appointed afterwards under the 13 & 14 Vict. c. 39. The difficulty attending the reception by the colonies of transported convicts having increased, the stat. 16 & 17 Vict. c. 99, finally abolished the punishment of transportation for less than fourteen years, and substituted imprisonment and transportation for life, a system at home for a term of years giving the accused power in all cases to substitute such penal servitude for transportation.

Before this last statute was passed, a system had for some time prevailed with respect to well-conducted convicts (wh, although sentenced to transportation, had been kept in the expectation of granting them free pardons, generally at the expiration of half their sentence of transportation. As the continuance of the same system under the last-mentioned statute seemed likely to cause serious evils, it was at the same time desirable to encourage good behaviour in convicts, it was determined to try the experiment of retaining some control over them in cases where they were set at liberty before the expiration of their original sentence. With that view the 19 Geo. iv. c. 3, by order of the secretaries of state, to grant any convict a licence or ticket of leave, to be at large during such portion of his term of transportation or imprisonment, and upon such conditions, as may be thought fit, such licence being also revocable at pleasure.

Finally by the stat. 20 & 21 Vict. c. 3, the sentence of transportation is entirely abolished, and the sentence of penal servitude substituted; but the statutes which have reference to the transportation of convicted persons, whence reference to penal servitude, is that the name alone is changed.

**SEXUAL SYSTEM, in Botany, is the name given to the method by which Linneus arranged the Vegetable Kingdom. In this system plants are divided into twenty-five classes, each of which is divided into family, genera, and species. The following are the classes:
I. Flowers with Stamens and Pistils.

Class 1. Monandria; flowers with 1 stamen.
2. Diandria.
3. Triandria.
4. Tetrandria.
5. Pentandria.
6. Hexandria.
8. Octandria.
10. Dodecanandria.
13. Polyantha; 20 or more stamens inserted into the calyx.
14. Didynamia; 4 stamens; 2 long and 2 short. [Corigiara.]
15. Tetradynamia.
16. Monadelphia; flowers with the filaments of the stamens united in one set.
17. Diadelphia; flowers with the filaments of the stamens united in 2 sets. (In this class the flowers are placed on the receptacle.)
18. Polyadelphia; flowers with the filaments of the stamens united in 3 or more sets.
19. Syngenesia; flowers with the anthers of the stamens united.
20. Gymandra; flowers with the stamens and pistils combined. [Ochridiello.]
21. Monoeia; flowers with the stamens and pistils on the same individual.
22. Dioecia; flowers with the stamens and pistils on different individuals.
23. Polygama; flowers perfect and unisexual, on the same or on different individuals.

III. Fructification concealed.

24. Cryptogama.

It will at once be seen that this system is exceedingly artificial, and that the great object of arrangement and classification in natural history is not attained by it. The effort of the naturalist in all systems should be to bring together those objects which most resemble each other, and to separate those which differ. A classification like the above, which takes only one organ or part of an organized being as a means of arrangement, is therefore certain to frustrate the great aim of the systematist, to produce an evident and artificial classification such as the above can be tolerated is that of convenience in finding out the name of any particular object. It was undoubtedly this that led to the general adoption of the sexual system of Linnaeus by botanists. It is now however fast falling into disuse; and our catalogues of plants and annals of indigenous Floras are written on the plan of the Natural System. Linnaeus divided the above classes into orders in the same artificial way. The orders in the first thirteen classes were founded on the number of styles or stigmas in each flower. Thus, flowers having one style were placed in the order Monogyna, those with two in the order Digyna, those with three in Trigyna, and so on. Thus the names of the orders are repeated in each of the thirteen classes. In the remaining classes however, points of structure are adopted. In Didynamia the orders are two, according as the fruit is 4-lobed or caparisan. The first order is called Gymnogyna, and the second Angio sperma. These names were given by Linnaeus under the erroneous supposition that the 4-lobed ovaries were as series of naked seeds.

The class Tetradynamia was divided into two orders, according to the form of the fruit, Siliculose embracing the species with the fruit a silice, and Silicinos those with a silice.

In the classes Monadelphia, Diadelphia, and Polyadelphia, the number of the stamens was made the text of the orders, and these were named as the classes. Thus we have the order Decandra, class Monadelphia, and the order Decandra, class Diadelphia.

With regard to Syngenesia the following plan will afford the best idea of the nature of the orders:

Order 1. Polygama Equalis.—Flowers all hermaphrodites.

Order 2. Polygama Superfusa.—Flowers of the disc hermaphrodite, those of the ray pistilliferous and fertile.

Order 3. Polygama Frustanae.—Flowers of the disc hermaphrodite, those of the ray staminiferous.

Order 4. Polygama Frenesia.—Flowers of the disc staminiferous, those of the ray pistilliferous.

Order 5. Polygama Segmenta.—Each floret having a separate involucre.

Order 6. Monogama.—Anthers united, flowers not compound.

This large class thus divided by Linnaeus forms the natural order Compositae, and has been recently subdivided in a much less artificial manner than in the orders above given. [Courvois.] The class Gymandra was divided into orders by the number of the stamens. It includes the natural orders Orchidaceae and Aristolochiacae.

The classes Monoeia and Dioecia are also formed into orders according to the number of stamens, and the orders are again named as preceding classes. Thus we have order Diandria, class Dioecia, etc.

The class Polygama has the following orders:

Order 1.—Monocarp.—Hermaphrodite, staminiferous, and pistilliferous flowers on the same plant.

Order 2. Dioecian.—Flowers on two plants.

Order 3. Triocarpia.—Flowers on three plants.

The Cryptogama were divided into the orders:

Filiaca.
Ferns.
Musei.
Mosses.
Hepaticae.
Liverwortz.
Lichenes.
Algae.
Sea-Weeds.
Fungi.
Mushrooms.

For the arrangement of the vegetable kingdom, according to the Natural System, see the articles Exoeae and Enoeae.

SESSIONS. The statutes 18 & 19 Vict., c. 45, has amended the procedure in Courts of Quarter Sessions, by prescribing uniformity of time for giving notices of appeal; by conferring extensive powers of amendment; a large discretion as to costs; and by enabling them to refer matters to arbitration. By the statutes 11 & 13 Vict., c. 75, these Courts, in common with the Courts of Oyer and Terminer and Gaol Delivery, are empowered to reserve questions of law for the consideration of the Court of Criminal Appeal; and by the statute 12 & 13 Vict., c. 46, the powers previously given to Judges to order payments by way of reward for the apprehension of certain offenders was extended to these Courts, the compensation to one person in no case to exceed $5. The statute 12 & 13 Vict., c. 16, makes further provision for the holding of petty sessions in criminal matters, and declares that every sitting and acting of justices, or of a stipendiary magistrate for a city or borough, having a separate commission of the peace, shall be deemed a petty session. The fees of justices, their charges, &c., are fixed by the statutes for by the 11 & 12 Vict., c. 43, and 14 & 16 Vict., c. 56. See further Juvenile Offenders, S. 2; Justices of the Peace, S. 2.

SEYBENITE. [Mineralogy, S.1.]

SHAKESPEARE. [Mineralogy, S.1.]

SHAKHOFSKY, PRINCE ALEXANDER ALEXANDROVICH, a prolific and popular Russian dramatic author, was born in 1777, at a village in the government of Smolensk. He entered the army in 1792, but in 1801 obtained the more congenial appointment of one of the directors of the theatre. The war of 1812 recalled him to the army and to the command of a regiment of Cossacks, but after its conclusion he resumed the duties of management. He retired with a pension in 1816, and died in 1846. During his lifetime Prince Shakhoovsky was the most conspicuous of Russian dramatic authors, and his plays were among the most fashionable in the theatres at St. Petersburg and Moscow. He achieved his greatest originality and his most successful efforts. SHAP. [Westmorland.]
SHARPE, DANIEL, F.R.S., at the time of his decease president of the Geological Society, was born in London in 1806. His father who died a few weeks after his birth, was sister to Samuel Rogers the poet. He was educated at Walthamstow, and as a boy early showed a taste for the study of natural history, but he did not commence serious researches until he had been admitted a Fellow of the Geological Society in June, 1829. In that year he gave his first memoir to the society, on a new species of Ichthyosaurus, I. grampius, which, however, it afterwards appeared had previously been described by Cuvier. The subject, however, was a new one to Mr. Sharpe, and it was an open question to the Geological Society a series of memoirs on the rocks of the neighbourhood of Lisbon and Oporto. The first is a mere sketch of the general arrangement of the tertiary and secondary rocks by a young and intelligent geologist; the second, on the same subject, is fuller and more definite, but not sufficiently complete in the determination of fossils to fix the precise age of the strata described. It contains, however, in an appendix, some observations of great value on the 'cylinders' of Lisbon, and on the general Proceedings of the Geological Society for 1836, on which the present paper is founded, but with omissions, alterations, and additions, the following just remarks occur on this subject:—"In the present state of knowledge regarding that country, it is impossible to deny that this may be the case, but it must be remembered that the few remains of plants discovered in these strata are considered by palaeontologists to present characters indicative of 'carbiferous' age; and even those geologists who most strenuously support the so-called uniformitarian doctrines, incline to attribute the peculiar position of the coal to one of those great inversions of the strata so frequent in highly disturbed districts of all ages, from paleozoic up to tertiary time." The fourth paper commences with a succinct sketch of the general geology of Portugal, and goes on to define the limits of the secondary rocks north of the Tagus, both by stratigraphical and palaeontological evidence. Long before this paper was read, Mr. Sharpe had acquired, much original skill and knowledge as a palaeontologist, and on palaeontological principles he now established the existence of cretaceous and Jurassic rocks in the country described. The whole formed an excellent sketch of a hitherto undescribed country, and up to this date British geologists are chiefly indebted to these memoirs for the knowledge they possess of a land where the science is almost uncultivated.

Between the years 1842 and 1844 Mr. Sharpe gave to the Geological Society, on the Silurian and Old Red-sandstone rocks of Wales and the north of England, territories previously chiefly illustrated by the labours of Professor Sedgwick. The first of these is 'On the Geology of the South of Wexfordshire.' Part of this paper describes the ranges of the Comiston limestone. Mr. Sharpe identified it by its fossils forming part of the Lower Silurian series, but did not determine its actual horizon. In 1839 Mr. James Garth Marshall, F.G.S., in a paper read before the British Association, placed it on the parallel of the Cambrian series, and said "it is impossible to separate by their fossils, the Bala rocks were the equivalents of the Llandeilo flag and Caradoc sandstone. This sagacious determination has since been confirmed by Mr. J. W. Salter, F.G.S., as regards the Caradoc sandstone, the fossils of Bala rocks have also been found in the sandstone of Sir Roderick Murchison in Shropshire being the same.

The more elaborate paper of 1844 is accompanied by a geological map of North Wales, and has been considered as showing the results of a new palaeontological determination of the age of rocks, and, in this case, at least, the time he allowed himself to map North Wales was too short for the satisfactory elucidation of the problems he proposed to solve.

Pursuing at intervals these subjects, Mr. Sharpe produced in 1847 an elaborate analysis and comparison of the Silurian fossils of North America, collected by Sir Charles Lyell, with those of Great Britain, and confirmed the views of the two countries. In a paper read before the Geological Society Mr. Hall, that the American Silurian strata, like the British, consist of two great divisions, namely, upper and lower.

While engaged in these investigations, Mr. Sharpe's attention was drawn to the subject of the slaty cleavage and associated phenomena, and he determined to give a full account of the Red-sandstones, the North of England, the Highlands of Scotland, and Mont Blanc. In 1844, 1845, 1852, and 1854, he produced four memoirs on these subjects, the two first and the last of which he published in the 'Quarterly Journal' of the Geological Society and the 'Transactions' of the Royal Society. These questions had previously been made the subject of special investigation by Professor Sedgwick, Mr. Darwin, and Professor Phillips. It has been said that the knowledge of slaty cleavage at that date Mr. Sharpe generalized too largely; and though this may be the case, an attentive perusal of the memoir of 1846 proves that in some important points he materially advanced the subject at that date in the direction to which the labours of Mr. H. G. Sorby, F.G.S., have since tended. He attributes the cleavage of rocks, and consequent distortion of fossils, to pressure perpendicular to the planes of cleavage, and asserts that rocks are expanded along the cleavage planes in the direction of the dip of the strata. In the communications of 1845, the doctrine that pressure is the cause of cleavage is still more distinctly insisted on, and remarkable instances are given, in which pebbles were observed which appeared to have been compressed and elongated in the planes of cleavage of the rocks in which they occurred. The doctrine is illustrated by Dr. Sorby, in the 'New Edinburgh Philosophical Journal,' that the fine particles composing the slaty rocks are arranged lengthwise in the direction of the cleavage planes. Deep-seated faults, in which the passage from one bed to another, to beds of different lithological character offering different degrees of resistance to pressure. The idea that cleavage may be due to crystallization action is altogether repudiated. It must be admitted, however, that no adequate investigation has yet been instituted of the relations of crystallization to the greater structures of rocks. We are as yet uninformed whether there are or are not jointed structures on the great scale, resulting from the coincidence of crystallization planes in comparatively large areas, as some of the phenomena exhibited by the Jewish mountains and by certain serpentines, tend to indicate. The two last of the series of Mr. Sharpe's papers on these subjects, published in 1850 and 1854, describe respectively the cleaved and foliated rocks of Scotland and France, and the author has chiefly devoted to the development of his theory of the great 'cylinders' or arches, in which he asserted that the laminae of cleaved and foliated rocks lie. In these memoirs he made no advance beyond his previous ideas, for he attributed the phenomena of cleavage and foliation to the same causes as he had before denied. However, though he indicated the fact, he gave no explanation of the reason of the occurrence of planes of cleavage and foliation in arched lines, a subject that has since been acutely and ably discussed. The author, in his latter paper, seems not far distant. In the paper on Mont Blanc he remarks that Mr. Sharpe explains and corrects for the first time, we believe, the remarkable error of Samurac, in representing the
cavage of slate, wherever they occur in the Alps, almost invariably as stratification; having mistaken the planes of cleavage for those of bedding, and regarded the latter as a series of parallel joints. But while showing that this systematic error runs throughout the whole of Sauvage's volume, he shows also that Sauvage's observations, even when his conclusions are erroneous, are always accurate and instructive. He was led into the error from observing the analogy between the foliation of the schists and the cleavage of the slate, and he was convinced of the correctness of his definition of cleavage for many years afterwards. Mr. Sharpe points out "after correctly distinguishing cleavage planes and foliation, Mr. Sauvage has been led to class the foliation of crystalline rocks with the latter instead of the former; thus proposing to unite two phenomena of totally different origin, while they separated those which are really analogous, and probably due to one and the same cause."

Besides these memoirs Mr. Sharpe contributed to the Geological Society various papers on special subjects, "On the Quartz Rocks of Macculloch's Map of Scotland," "On the Southern Borders of the Highlands of Scotland," and various paleontological communications; "On the genus Truncatia," the "Abandonment of marlstone purpurine, and the Cretaceous beds of Portugal," "On the genus Nerinea," and a note on the fossils of Boullonnais, appended to a paper by Mr. Godwin Austen on that district. He also furnished several parts of the Zoological Society's scheme of the Palaeontological Society. "On the Fossil Remains of the Moluscus found in the Chalk Formation of England," and on this important work he was still engaged when he met with the accident that caused his untimely death.

Mr. Sharpe was a man highly endowed with the gifts of a poet, with the powers of an artist, with the force of a man, and with the knowledge of a scholar. His life was full of activity and usefulness. Besides his natural powers, his habits of continuous study, the necessities of the times, his peculiar health, the prejudice against his religious opinions, all combined to make him a contributor to science.

Anxious however to acquire a wider reputation, he, in 1788, came to London. Here he found in Edmund Burke a kind friend and adviser. Burke introduced him to Sir John Reynolds, who treated him with much cordiality. Mr. Shee recommended him to the President of the Royal Academy, who became for the first time a contributor to the exhibition, sending a 'Portrait of a Gentleman,' and a 'Head of an Old Man.' Though he did not become a popular portrait-painter, he was far from unsuccessful; for some time at least, obtain many sitters from among the aristocracy or nobility of the land, and steadily into a good and tolerably lucrative practice, towards which his geniality of manners rendered him valuable service. In 1798 he was elected an Associate of the Royal Academy, and he now deemed his position sufficiently secure to venture on taking the house in Cavendish-square, which Romney (whose successor he aspired to become) had built for himself when in the height of his celebrity. In this house Shee continued to reside until failing health compelled him to make some alteration in his dress and remove to a country seat, which he held for a century later. This change of residence was attended with an improvement in his professional standing. He had painted a good many portraits of the leading actors, and of the leading politicians in the last generation of great politicians, which had attracted attention at the exhibitions, and rendered him the object of some attention. Shee's next move was to his fashionable house. That he was fast making his way was sufficiently shown by his election as Academician in 1806, only two years after his election as Associate: his presentation paper was "On the formation and relations of the Bench." From this time his career was marked by few changes or vicissitudes. Like most of the English painters of the time, during the short life in the war between France and England he went to Paris to examine the art-treasures which Bonaparte had collected in the Louvre and elsewhere. The biographers find little to notice until he appeared before the public in the character of a poet, by the publication, in 1805, of his 'Rhymes on Art, or the Remonstrances of a Painter,' a work which his author described as "a poem on painting, in which, more particularly, the early progress of the student is attempted to be illustrated and encouraged." A second part of it appeared in 1809. Byron praised the poem, and it was a good deal read and quoted at the time; and painters still occasionally garnish their literary essays with a stanza from it; but its vitality has long since departed, though it has an easy flow of rhyme, and is not without more substantial merit, and the notes are occasionally valuable. Again, on the occasion of the exhibition in 1821, Mr. Shee exhibited at the British Institution, and a 'commemoration dinner' in honour of Sir Joshua being given by the directors of the institution in May 1803, at Will's Rooms, the prince regent presiding—Mr. Shee invoked the interest of his friends, and fell in a notice, now entitled 'The Commemoration of Sir Joshua Reynolds, and other Poems.' His next appearance as an author was under, to himself, mere exciting circumstances. He had written a tragedy called 'Alasco,' the principal character of which he deemed to be particularly suited to the historical powers of his friend Kemble; who agreed to act it. But it happened to be the first tragedy which fell under the hands of Colman, the new licensor of plays, and he regarded himself as being perhaps too young and inexperienced to act the moral purity of the play-going public, and was not permitted to permit it to be performed so long as it contained certain bits of declamation about liberty, and denunciations of despotism, as well as one or two expressive lines. To the expulsion of these the author resented the right to have his tragedy referred to the Lord Chamberlain himself against the decision of his deputy. But the chamberlain (the Duke of Montrose) declining to examine that on which his deputy had "reported," replied, with the observation of grammar, 'I do conclude, that at this time, without going to personal discussions, the tragedy should not be acted.' Shee however was not to be silenced, and resolved to shame his censors by printing his tragedy, though it was not allowed to be performed. It was printed in a secret manner in which the facts were set forth with considerable warmth, while all the prohibited passages were printed in italics. The tragedy itself is forgotten now, but it will be referred to by writers of literary and political history for illustrations.
of what was prohibited as politically dangerous in London so late as 1825. The censor certainly did his work carefully. Treason is seen to lurk sometimes in single words—often in single lines, such as—

"Or question the high privileges of oppression."

Even the mention of—

"Some slanderous tailor of state, some looting, full, unwise man's deputy,"

is thought to bode mischief, and is expunged accordingly. This was Shee's later appearance as a poet, but once later he tried his hand as a novelist.

Literature however was but his amusement. During all these years he had been steadily making his way to a fore-

men position in the fashionable world of the times of the day. The mantle of Reynolds had not fallen on his suc-

cessor, but Lawrence's easy gracefulness of style concealed his deficiencies from the eyes of his contemporaries, and he reigned in undisputed supremacy. But Lawrence could not alone supply the demands of the titled and wealthy claimants for the immortality of portraiture; and though among the political and literary celebrities Phillips perhaps was most in repute, his gay colour and polished manners undoubtedly rendered Shee second favourite with lords and ladies.

On the death of Lawrence in 1830, he naturally aspired there-

to succeed him not only as a fashionable portrait painter, but also as president of the Royal Academy. Wilkie became his opponent, but though of course there could be no com-

petition between their respective powers of the two men, the academicians felt that Shee's fineness of speech and courtly address were of far more consequence in the academic chair than more eminent artistic abilities with reserved manners and a faltering tongue. Shee was elected president by a large majority, and soon afterwards received the honour of knighthood. He is said to have filled all the duties of his office with zeal and ability, and his official eloquence on those public occasions which it called forth was much admired. He continued to paint until 1846, in which year he exhibited for the last five time pictures; but his powers had been for some years evidently failing. He now, on the ground of inability to discharge its duties, resigned the presidency, but at the unanimous request of the academicians he was induced to withdraw his resignation, and he continued to hold the office till his death, which occurred on the 13th of August 1850, in his eightieth year.

Sir Martin Archer Shee will not rank among the great portrait painters of the English school. He is deficient in depth and force, in intellectual expression and in character-

isation. But his colour is often pleasing though too florid, and his figures have an air of ease and refinement; and his pencil has undoubtedly preserved the best portraits of many of the most distinguished contemporaries. He occasionally painted historical figures and fancy subjects, but none of them won much attention. He was an accomplished gentle-

man rather than a great painter.

H.C. W. RICHARD, M.A., F.R.S., F.R.A.S., was born at Leeds, July 30th, 1794. His father was engaged in the cloth manufacture, and destined his son for the same pursuit. At the age of fifteen however, and after an ordinary school education, the son discovered his own preference for a learned profession, and the father accordingly placed him under the care of the Rev. James Tate, M.A., the master of the Grammar-school of Richmond in Yorkshire, well known as one of the most successful teachers of this science in the country as an elementary case. He remained until 1812, when he was removed to Trinity College, Cambridge. He took his degree with honours in 1816, obtained a fellowship in the next year, and proceeded to study for the bar, to which he was called about 1822. A weakness of sight, to which he was always subject, is sup-

posed to have been the principal cause of his not practising law; but it must be added that his share of his father's property placed him in easy circumstances, independently of his own, and his anxiety for science had become very decided. He took orders about 1824, and devoted himself entirely to astronomy. He became a fellow of the Royal Astronomical Society in 1824, and was elected into the Royal Society on the 1st of April 1830. Of the followers of the second generation of the activative body. His leisure, and his desire to help the young astronomer so long as he wanted advice and guidance, gave a peculiar value to his services, and a peculiar utility to his career.

Mr. Sheepshanks resided in London till about 1843, when he removed to Reading, where he died of apoplexy, April 4th, 1855. There is much reason to suppose that his life was shortened by his labours exertions in the restoration of the standard scale of linear measure. Though an ardent advocate of the opinion which held for existence during the first half of his life, but gradually became victorious in the second, he never took any public part in a political question, except that of the Reform Bill. He was the first to propose a boundary line to fix the boundaries of the boroughs under the new system of representation. His reading in politics and history is stated to have been extensive; and he was espe-

cially partial to military matters, with which he was very well acquainted. He exhibited in the British Museum a portion, and no inconsiderable portion, of his studies. To this must be added literature and poetry, to which he was much attached. He never abandoned classical reading, and those who knew him best were often surprised at the extent to which he had cultivated modern literature.

But his subject was astronomy, and his especial part of that subject was the ~astronomical instrument. His reputa-

tion among astronomers on this point, and the articles by which he contributed to the ~enny Cyclopedia, have

induced an expression of regret that he did not draw up a full treatise on a matter which he had so completely fatihmed.

Mr. Sheepshanks was engaged in active efforts on several special occasions, to which we make brief allusion. In 1828 he joined Mr. Airy, now Astronomer-royal, in the pendulum operations in Cornwall, and suggested some of the most important corrections to the operation of pendulums that are active in the establishment of the Cambridge Observatory. In 1833 he was consulted on the part of the admiralty with reference to the edition then preparing of Groomebridge's Circumpolar Catalogue: the remit was the publication of a work that would be of much more value than it would otherwise have appeared in. In 1832 he also interfered in a matter to which, connected as it is with personal differences, we can only here allude, as eliciting much information on the subject of equatorial instruments in general, a remit which is entirely due to the part taken by Mr. Sheepshanks. In 1838 he was engaged in the chro-

nometric determination of the longitudes of Antwerp and Brussels; and in 1844 in those of Valetta and Kingstown in Ireland, and Liverpool. In 1843 a subject of the Liverpool Observatory led him into a controversy, his pamphlets on which will be useful study to those who are interested in astronomical instruments. He was always in active member of the Board of Visitors of the Royal Ob-

contended in defence of truth and justice, as they appeared to his mind.

.. SHEL

RICHARD LALOR, the son of Mr. Edward Sheil, a merchant of Cadiz, was born in Dublin in the year 1793. His father was a Roman Catholic, and he was educated in that religion at the Jesuit College of Stonyhurst, Lancashire. He became ill of his lungs when he was an undergraduate of the Trinity College, Dublin, where he graduated with distinction. He next proceeded to London, and entered himself at Lincoln's Inn to study for the English bar, which he had been recommended to. The late T. Campbell, a great advocate, had a high opinion of his father's means through a dispassionate character. It is said that he induced his father to change his residence and return to Ireland, where he was called to the bar in 1814. He destroyed the expenses of his years of study by the successful tragedy of 'Adelaisa,' in which Miss O'Neill performed, and by those of the 'Apologies,' 'Bellamiris,' 'Evadne,' and 'The Huguenot.'

At this time he also contributed some 'Sketches of the Irish Bar' to the 'New Monthly Magazine,' then edited by Mr. T. Campbell. It appears he was a very promising young man, and a speaker, he never heartily devoted himself to a deep study of so dry a subject as the law, and that his professional income in consequence was not large. He was not a lawyer but an orator by nature, and he found his forte in the literary stage for the display of his talents than the law courts of Dublin. As a Roman Catholic too he laboured under the civil disabilities which, though modified from what they had been, still shut the doors of the House of Commons against him, and his religious principles induced him to take an active part in all of them. It was, however, against the bill introduced for its suppression. The bill however passed; but it only served to inflame his religious zeal and to rouse his oratorical powers to such a pitch of vehemence invective against the government, that a prosecution was commenced against him for seditious language. The illness of Lord Liverpool however transferred the premiership to the hands of Mr. Canning, who wisely ordered the prosecution to be abandoned. In 1829 Mr. Sheil took an active part in procuring the return of Mr. O'Connell to parliament, as member for the county of Clare, and also addressed the great meeting held at Penenden Heath for the purpose of resisting the Roman Catholic Emancipation Bill. In 1839, soon after the passing of the Relief Act, Mr. Sheil was returned to parliament for the county of Milborne Port, by the influence of the late Marquis of Anglesea, who, while holding the lord lieutenantcy of Ireland, had noticed his career, and who thus turned the restless agitator into a peaceful citizen and a useful magistrate. His oratorical powers were appreciated, and he soon became one of the most popular and active speakers in the House of Commons, though the matter of his speeches never rose to a level with the brilliancy of illustration and force of impassioned declamation with which they were adorned. In 1830 he was again returned for Milborne Port, and in 1831 for the county of Louth. After the passing of the Reform Act, which gave much dissatisfaction in Ireland, Mr. O'Connell commenced agitating for repeal, in which Mr. Sheil at first ran the least risk, as his biographer, Mr. T. M'Cullagh, asserts, that it was "in point of fact but short-hand for just and equal government in Ireland." In December 1832 for the first reformed parliament he was chosen to represent the county of Tipperary, where he had acquired some extensive landed influence by his second marriage with the widow of Mr. E. Power of Gurteen, on which occasion he adopted that lady's maiden name of Lalor. In 1834 the Grey ministry introduced an Irish bill, which caused a great deal of excitement among the Irish members, among whom was Mr. Sheil, but a report came from the house that several of them had expressed a wish that it should be carried, "or there would be no living in Ireland," an expression which Mr. Sheil and on Lord Althorp being appealed to, he replied that he had no personal knowledge of any such expression, but had heard it, and though he could not give up the names, he would tell any member who asked whether he was one. On

Mr. Sheil making the inquiry, he replied he was one who had been mentioned. Mr. Sheil denied it at once: a parliamentary committee was appointed, and Mr. E. Hill, who appeared before the committee to support the allegation, confessed that he believed that he had been misinformed. In the same year, which was a period of great agitation, he was a signatory to the Compact, a term applied from a phrase of his own, in which he hoped "that no minor differences would mar their compact and cordial alliance." In 1838 he was offered office by the Melbourne administration; at first the clerkship of the privy council, and then, it was reported, he became one of the commissioners of Greenwich Hospital, and never again advocated repeal. In 1839 he was made vice-president of the Board of Trade; and was also sworn a member of the privy council. He read the bill for the establishment of the post office on whom that honour had been conferred since the reign of James II. In June 1841 he was appointed judge-advocate-general, when he resigned the seat for Tipperary for that of the borough of Dungarvan; but he held office only till the following September, when his party were superseded in office by the late Sir Robert Peel. On the advent of Lord John Russell to power in 1846, Mr. Sheil was appointed to the mastership of the Mint, which he filled until November 1850, when he was sent as agent of the British minister at the court of Tuscany. His health had been broken down for some time, and he had rarely spoken in the House of Commons for the two or three years immediately preceding his retirement from parliamentary life. Although the appointment to Florence was one of the most important in his life, he regarded it as nothing less than expiration and an extinction of what might have been a growing reputation, yet he submitted not so much with a feeling of philosophic indifference as in a joyous spirit, as though he felt that his diplomatic post would prove a great Traveller's Shiel, by W. T. M'Cullagh.)

SHELBURNE. [Novo Scotia.]

SHELLEY, MARY WOLLSTONECRAFT, daughter of William Godwin and wife of Percy Bysshe Shelley, was born in 1792. In 1816, while in Italy, she wrote her powerful and striking romance of 'Frankenstein,' which commanded an extensive popularity in England, and is still a favourite with the admirers of the wild and wonderful, while the extremely ingenious and consistent development of the character of the monster combines with the monster even the most fanatical regard for the theory of the book. Though Shelley was a prolific writer, she was not a workman, and the elegance of her style was not always removed by the book. She was a student, and the health of the publisher with affectionate solicitude, which she gratefully acknowledged and repaid. Just previous to his unfortunate death however she had finished 'Valperga,' a novel, afterwards printed in 3 vols., for which Shelley says in one of his last letters that she had been offered 400l., which he designed for the relief of the necessities of his father-in-law, W. Godwin. After her husband's death she published 'Falkland,' 'The Last Man,' and 'The Fortunes of Perkin Warbeck,' each in three volumes. She also wrote a 'History of Rambles in Germany and Italy,' an account of her journeys with her husband. In 1829 after the publication of his poetical works, with a few biographical notes added, in which the more offensive passages of 'Queen Mab' are omitted; and in 1840 a selection from his letters and a few specimens of his prose writings. In all these, to which a few poetic, but no section devote to his goodness of heart and the other amiable qualities which she states invariably secured him the love of all who knew him. She died in London, on the 1st of Feb-

SHIPPING. [Trade, Shipping, &c, &c.]

SHIPS. Nearly all the statutes mentioned under this head (Sails, v. 17, c. 150, and Vic. C. 150). The law relating to shipping, to the contracts arising from the employment of ships, and to the mutual duties and obligations of masters, masters, passengers, and seamen, remains, nevertheless, almost unaffected; the pro-
visions of the repealed statutes being, in principle, though not always in detail, re-enacted by the statutes about to be mentioned.

The most important of these is the Merchant Shipping Act, 1862, which is amended by stat. 16 & 19 Vict. c. 91; in the next importance, the Passengers' Act, 186 & 19 Vict. c. 119. The Act relating to bills of lading, and that concerning admiralty jurisdiction on the County Courts, have been almost entirely transferred to [Landau, Binn or; &c., County Courts (S, C,)]. It would be quite impracticable to give any detail of the provisions of these Acts, which constitute complete codes in themselves, and which must be referred to by every one who wishes to know anything of the subject.

It is necessary to mention here, however, the statutes which have repealed the Navigation Acts, whereby, it was said, "the constant increase of English shipping and seamen was not only encouraged, but rendered inavoidably necessary.

These Acts were by various statutes maintained down to a recent period; their leading feature being to secure the exclusive trading by which it was thought British shipping and navigation were encouraged. The first step in favour of free trade was effected by the statute 12 & 13 Vict. c. 29, by which the exclusive privileges of British ships were limited in effect to the coasting trade of the United Kingdom, the trade with the Isle of Man and Channel Islands, and the coasting trade of the colonies. But this Act has been almost entirely repealed by the statute 16 & 19 Vict. c. 107, by which the entire trade has been thrown open to vessels of all nations.

The Board of Trade exercises a general supervision over all matters relating to merchant ships and seamen, and the carrying into execution the statutes in force relating to the protection of seamen, regulations governing the registers of Merchant Seamen, as to trade and navigation, and originates inquiries and considers reports made to it by its inspectors and other officers.

It exercises a partial control over local marine boards, and may lay down rules as to the conduct of examinations, and the qualification of applicants for the posts of masters of masters and mates of passengers' ships. It grants licences to persons to engage or supply seamen or apprentices for merchant ships; adjudicates on claims for seamen's wages, investigates cases of alleged wanton and reckless neglect in master mariners and appointees officers to report on the condition and efficiency of steam-vessels and their machinery. These and its other duties, and the mode in which they are exercised, are defined in the Merchant Shipping Act, and other statutes above referred to.

SHIPSTON ON STOUR. [Worcestershire.] SHIPWRECKS AND LIFE-BOATS.

That wrecks are numerous, is a fact well-known to a seafaring nation like ours, and where the coast-line is so nearly bare, regard being had to the perils of the deep, will of course be admitted; but that nothing can be done to lessen their frequency, would be a hopeless theory of which we ought to be ashamed. Supposing for the sake of fixing the idea, that we have or may one day have, a vessel of the most modern and powerful principle, and that a knowledge of winds, waves, currents, whirlpools, shoals, reefs, and sunken rocks, on the part of meteorologists and hydrographers; that others are caused by the incompetency of captains and mates; that others again result from the insubordination, carelessness, ignorance, or obstinate hatred of seamen; that a fourth group are due to the deficiency of lighthouses, beacons, and buoys; and that the remainder arise from want of ready assistance to ships which, though placed in the track of possible disaster, have not the means of science at command; knowledge of winds, waves, currents, whirlpools, shoals, reefs, and sunken rocks, on the part of meteorologists and hydrographers; that others are caused by the incompetency of captains and mates; that others again result from the insubordination, carelessness, ignorance, or obstinate hatred of seamen; that a fourth group are due to the deficiency of lighthouses, beacons, and buoys; and that the remainder arise from want of ready assistance to ships which, though placed in the track of possible disaster, have not the means of science at command.

A dismal story, indeed, does the "Wreck-chart of the British Islands" tell, as published by the Admiralty, and afterwards in the Life-Boat Journal. It may be designated a truly distressing map. Every wreck on our coasts has its little black mark; and the aggregate of such black marks reveals the extent and magnitude of the wreck. And that black spot indicates a vessel wrecked, and that + indicates a vessel so seriously damaged as to need to discharge cargo, we look eagerly for the relative numbers of these latter cases as an index. It is saddening to see how numerous are the fatal black marks, and how the black spots are numerous because the coast is dangerous; at others, because the congregating of ships is very great.

And if it be asked, "What ratio did 1857 bear to previous years, in respect to these calamities?" it is encouraging to know that on the whole it was favourable, fewer lives were lost and more were saved, than usual; yet still our coasts saw not fewer than 1143 wrecks of ships. The lives lost numbered 638 (in 1854 they amounted to 1460), and the number of lost vessels was 1866, of which 982 were by life-boats, 612 by loggers, coast-guard boats, &c., 507 by assistance from shore with ropes, mortar-apparatus, &c., 948 by ships' own boats, and steam-vessels, and 8 by individual exertion. It is, however, a matter of regret to see that 22 vessels, members, happened on our own coasts—on the coasts of the most busy maritime islands in the world; where, if there be liability of disaster through the vast congregation of shipping, there ought, on the other hand, to be a corresponding improvement, in some degree, of search and human assistance. In examining the details of the chart, it will be seen, that, as usual, the line of coast between Dungeness and the Pentland Firth is the most fatal, and that the mouth of the Tyne takes the unenvied precedence of all other places, in the number of black dots and stars opposite to its name; next come the month of the Tens and the month of the Wear. These three rivers may be taken as the representatives of the district wherein three million tons of vessels are brought by sea to London yearly, excepting the services of several thousand collier ships, which sail to and fro, and add to the otherwise busy commercial trade of the Northumbrian and Durham ports. The mouth of the Humber, the Suffolk coast between Yarmouth and Southwold, and the coast of the South or Scilly Islands, will also be noted, for the movements of the Goodwin Sands, the Scilly Islands, Barnstable Bay, and Liverpool, are the portions of the English coast which present, in the next degree, the most numerous indications of ship-losers. The Welsh coast is thickly shrouded, especially in midsummer, from the Llyn Peninsula to the Mersey, and near the Firth of Forth, presents no large numbers; the western coast is, indeed, remarkably free, due probably to the less exposure to the winds which tend to drive ships upon our eastern seaboard, and Ireland present a tolerably equable distribution along the east and south coasts: less on the northern and western.

The annual report states that the year 1857 was a favour- able one with respect to shipwrecks, yet 437 vessels were totally lost, and 706 damaged. Of these, 500 vessels were of British ships; 33 were registered in British colonies; 213 were foreign vessels; and 72 were not known; the total amount of the tonnage of these ships was 218,570, and they were manned by 9019 sailors. Of the total wrecks, 63 were by collision, owing, in many cases, to the report of navigable, and the remains of a ship on the beach, or on the rocks, suggest the previous existence of a wreck, which, if recorded, might be of some use in the formation of a Statistical Society of the United Kingdom, where wrecks and near sinking-vessels can be the subject of inquiry, and the means of searching for survivors should they be lost.

Many enquiries into the causes of shipwreck have been instituted; and especially one by a Committee of the House of Commons, whose voluminous report resulted. But public attention was perhaps more fully drawn to the subject by the Duke of Northumberland, who, in 1850, offered a premium of 1000l. to the party who should suggest any means of preventing ships from being lost. This was successful, and has continued ever since. In the earlier part of this century, before the establishment of life-boats, it was suggested by a number of persons to induce the formation of Local Committees at the chief

* The Life-Boat; or, Journal of the Shipwreck Institution. Established by C. Knight, 60, Fleet-street; and to be had at the offices of the Lancashire, 14, John-street, Adelphi.
ports for a similar purpose; to maintain a correspondence, beneficial to all parties, with these Local Committees; to reward persons who render assistance to distressed ships or mariners; and to encourage the invention of new or improved boats, buoys, balls, rocket apparatus, and other means for saving life. The Society commenced a little work, in Numbers at twopenny each, which, at intervals, gives an epitome of all that is worth knowing on this matter.

A deserved meed of praise was given by a Quarterly reviewer of the "Life-Boat Institution," in that he has established, at his own cost, at the principal stations off the coast of his native county, "life-boats of an improved construction, and supplied with all the necessary apparatus and appliances, that may contribute most efficaciously in assisting, favourably in stimulating the humanity and activity of the neighbouring population, and from which the tourist, without being unseasonably sentimental, may derive his full share of satisfaction. The grave-yards which surround the stirring ruins and picturesque churches of mountainsous Northumberland, are full of the mournful records of youth cut off in its bloom, and manhood in its prime, by the tempestuous waves. Each stone has its own sad tale—of brothers found locked in each other's embrasures—a father who perished in a vessel abandoned by the perils of fate, united to his industry and affection, and undivided in death, swallowed up in the little craft that constituted the whole of their worldly wealth. He must be 'duller than Lethe's dull weed,' whose heart he could not read, the victim of as many struggles and their fate, and whose eye does not glinten when he hears of the ménongence which has done all that on that dangerous coast can be done to avert such catastrophes in future."—Quarterly Review, No. 194.

It is too much, however, has been said. This is to put a limit to man's ingenuity and foresight, which we should be sorry to admit until the desired end has been more fully attained.

An example—neither of the means for preventing shipwrecks, or for saving the lives of those who may be endangered by wreck—but for rendering aid to the poor fellows who may have lost all but life by such calamities, the "Shipwrecked Fishermen and Mariners' Royal Benevolent Society" deserves a word of notice. The scheme was formed at Bath in 1839 by Mr. Rye, who was impressed with the importance of affording relief to the widows and orphans of fishermen and mariners who might be drowned, and of assisting with clothes, food, and money, those who might be cast ashore destitute, but destitute at once of all the necessary of life. Aided by Sir Jahleel Brenton, at that time Governor of Greenwich Hospital, Mr. Rye succeeded in establishing a society, and in collecting a respectable fund. The society, in 1840, has 150 members, and the amount contributed last year in that same year, three fishing-boats were lost in Mount's Bay, involving the death of 30 persons, and the sudden impoverishing of 17 aged persons, 12 widows, and 36 children. A sum of money contributed to the bereaved survivors served to bring the uselessness of the society into notice. The Society progressed steadily. Between the years 1839 and 1864, it afforded relief to 30,000 shipwrecked persons, and to more than 14,000 widows, children, and dependants of fishermen and mariners, who had been drowned. The aid is not wholly eleemosynary; it partakes in some degree of the character of a provident fund. Primarily, the Society "boards, lodges, and conveys to their homes all destitute shipwrecked persons to whatever country they may belong, those who have lost all but their lives, or the means of subsisting, or the means of reaching those who have been drowned, and gives a gratuity to such members as, without losing life, lose or damage their apparel or boots by wreck or similar calamity. The longer the period during which a fisherman or mariner has been a member, the greater is the gratuity. Any widow and children in the event of his death by wreck or drowning. Every institution which fosters habits of provident forethought is worthy of respect and support; and the Society not only finds notice in one of the annual reports described. As the newly-charitable part of the plan, it ranks with a multitude of other praiseworthy modes of helping those who could help themselves.

It was found, however, in the course of years, that two societies—bearing the titles "National Shipwreck Institution," and "Shipwrecked Fisherman and Mariners' Royal Benevolent Society,"—were liable to be confused in the public mind; and a union or amalgamation became desirable. Accordingly, in the early part of 1855, the latter-named society transferred to the former all its property, assets, rights, and liabilities. The new "National Shipwreck Institution" at the same time changed its name to the "National Life-Boat Institution," to define more clearly the objects aimed at.

That the positive amount of good work rendered by the Life-Boat Institution is made manifest by the simple fact, that in 1857 alone the life-boats belonging to, or in connection with, the Institution, were the means of saving the lives of 300 persons, all of whom would probably have been lost but for such aid. The following is a list of the lives saved, for which rewards were given by the Society:

It may not be that these lives were all saved by the Institution; indeed such was not the case. In many instances the saving of life by the life-boats or other means did not involve any extraordinary risk, or the exercise of any remarkable skill or bravery, and it is only to such cases, whether performed by persons connected with the Society or strangers, that the rewards are distributed; and the list, therefore, only includes the cases of lives saved from shipwreck on our coast, in which the Society gave honorary or pecuniary rewards.

The life-boats belonging to, or in connection with, the Institution, in March, 1858, were no less than 70 in number, and there are 75 others provided from various sources, and not in connection with the Society. Considering that the boats usually cost from 100l. to 500l. each, the boat-carriages and the boat-houses about 100l., it will be seen that the amount of money thus sunk is something nearly as considerable as the Northumberland, the lifeboat or the Duchess of Argyll's 200l.; these are the counties most liberally provided. These boats, on an average, appear to be about 30 feet long by 6 feet broad, 2½ feet deep, weight 40 cwt., and are rowed by 8, 10 or 12 oars. The life-boats above adverted to, are purposely so constructed as to brave the peculiar dangers of a coast where shipwrecks are liable. Seventy years ago the construction of such boats began to attract attention; and in 1789 Mr. Greathead, of South Shields, constructed what may be deemed the original of all the life-boats since made. Cork was largely used in Greathead's boat to render it more buoyant; and since his time a light-tight cases, formed of India-rubber cloth, have been a favourite feature in many of the inventions. When the Duke of Northumberland offered the prize in 1860, no boat was placed on the market, considering the many modes of combining buoyancy with stability in boats. About 50 of the best of these models were placed in the Hyde-Park Exhibition. The prize was given to Mr. Beeching, of Yarmouth, for a boat, the construction of the boat which seemed to combine the greatest number of good qualities. Since that time a boat, invented by Mr. Peake, of her Majesty's Dockyard at Woolwich, has been more frequently adopted as a model than any other.

A boat built on the lines of the Greathead, in which there are numerous fittings necessary to render it workable: there must be a boat-house, in which to keep it sheltered from the weather when out of use; and a carriage wherein to wheel it to the place of disencumbering it in case of distressed or stranded ship. Moreover, there must be a crew of trusty men, able and willing to brave a raging sea, strong and resolute, to pull the oar under any stress of weather; and there must be a master or coxswain, exercising sufficient control to
command the men and direct their energies in a proper channel. It is the direct object of the present provision of life-boats and knoys, that the Life-Boat Institution has rendered service. A system of payment, partly in the nature of a salary, partly as a reward, is adopted, such as may induce steady men to render aid; and the local committee has found the object of the establishment is to be deferred, and in laying down the rules which are to govern the movements of the life-boat corps.

The exact mode in which a life-boat renders its useful service must depend, of course, on many contingencies of wind and tide. The following is an example:—On the 2nd of May, 1855, in early morning, the beachmen at Ramsgate heard alarms given, and saw signal-rockets fired on board the light-vessels moored off the Goodwin shoal. As the vessels were not in the perilous region. The Ramsgate life-boat (the property of the Ramsgate Harbour Commissioners) was speedily manned and equipped, and taken in tow by the Samson steam-tug against a rough wind and tide. The hapless ship was seen from the steamer with signals of distress flying, and apparently high and dry on the further edge of the Goodwin; the tide being low at the time, and a heavy sea on the edge of the sand. At a particular point the life-boat left the beach-tug and rounded towards the stricken vessel, but it was speedily found that the depth of water around the vessel was too small to permit a close approach by the boat. The men, therefore, waited until the in-coming tide favoured them a little; they went on; they ran on shore amongst the sand, they were dashed over the keel of the cutter, jumping overboard into the surf, waded to the ship, which they reached in an exhausted state. The ship was the Queen of the Teign, bound from Antwerp to Liverpool with a valuable cargo, of sugar, hemp, and seeds. When the crew of the ship saw the exertions of those who had undertaken to aid them, they descended from their vessel into a boat, jumped on the lee-side of the sand, and thence got into the life-boat. As soon as the tide had risen sufficiently to allow the steamer to approach the line was thrown on board here, and a communication being thus established, she was enabled to lay out an anchor to leeward, and subsequently to get her own large low-tide fast to the vessel. By these means the vessel was lost off from her dangerous position, and taken, in a leasy state, with four feet water in her hold, into Ramsgate Harbour.

Another example is worth noticing, as showing the recklessness of crews, and the probability that such recklessness frequently occasions loss of ships. On September 7th, 1855, the signals of distress were observed in the direction of the Holm Sand, off the Suffolk coast, during a strong easterly gale. The Pakfield life-boat immediately put off, towed by the Lowestoft steam-tug. Finding that it could not reach the vessel to be rendered assistance, the steamer opened fire on the ship, and a communication being thus established, she was enabled to lay out an anchor to leeward, and subsequently to get her own large low-tide fast to the vessel. By these means the vessel was lost off from her dangerous position, and taken, in a leasy state, with four feet water in her hold, into Ramsgate Harbour.

No part of our maritime system has, in recent years, attracted more attention than that which has just been illustrated—the personal character and conduct of the men employed. Who can tell the amount of misery which one hour of inebriety, one display of incompetency, may produce? The ship may be all that human art can effect, in strength and efficiency; the fittings and stores may all be that could be wished; the hatches may be good in kind and ample in quantity—and yet one slight manifestation of indiscretion or of unskilfulness, may give room for a catastrophe which will plunge scores or hundreds of human beings into a watery grave. This matter was taken up by the Legislature many years ago, and a great deal of money was invested in the system established in virtue of a statute presently to be noticed.

The life-boats of which we have spoken, are not the only means necessary for affording aid to stranded or wrecked vessels. There are others in use, but in no case as in the present is need is supplied; when a ship is in distress so near the shore as to be within reach of a rope, if means were at hand to throw it—while, perhaps, no boats are near the spot fitted to render the required service. The name of Captain Manby is intimately associated with the system of boats laid on shore for the purpose of conveying a rope to vessels in danger, and Manby's ingenuity was excited by a terribly distressing scene which he witnessed in 1807; when the Snipe, a gun-boat, was lost off Yarmouth; when sixty-seven persons were preserved, within sixty yards of land. The boats were five or six inches above the wreck, without a possibility of receiving assistance. Long before this, he had thought on the subject. He had, in 1783, thrown a line, by means of a small mortar, over Downham Church, in Norfolk; and it was known that he had been in the practice of the same. Manby was the first to put in practice a really available plan.

Let us see what is the end to be attained, that we may understand the mode of attaining it. A ship is stranded near the shore, say two or three hundred yards off, where there is a long beach, and boats cannot approach it; and the men of the vessel are drowned, or die of exposure. Sailors, unfortunately for themselves, are in too few cases swimmers; and even a swimmer has a poor chance for his life in such weather and such a sea as usually accompany these strandings of ships. The men generally choose the ship's boat as she is to be allowed her timbers will hold together, rather than strike out and endeavour to swim to shore. In such case their safety mainly depends on the establishment of some communication with the shore. Such communication was the object of Manby; and on the 3rd of March, 1808, a brig ran aground within a hundred and fifty yards of the Yarmouth coast; the crew lashed themselves to the rigging, and bore up against a furious storm as best they might—hoping almost against hope. All attempts to send off a boat to them failed. At length Captain Manby brought his mortar down from his residence to the coast, and succeeded in throwing a line over the ship, by which all the poor fellows were saved. Having thus given practical proof of what could be effected, Manby was instrumental in causing many mortars to be so applied on the coast. He frequently tried to obtain some recognition of his services from the Government; and in this matter he was more fortunate than many useful discoverers. He was unquestionably the first to adopt any means of communicating with vessels at sea. These boats have been tried in many vessels; and in many cases, both ships and boats have been saved by means of the ropes thrown out to stranded ships, through the agency of mortar-rockets. There are 196 places on the shores of the United Kingdom, where such apparatus is kept, mostly under the charge of the coast guard, who, from the peculiar nature of their other duties, are well adapted for this kind of service.

The articles transmitted to the Paris Exhibition of 1855, by the Life-Boat Institution, may be taken as a test of the present state of the art of this interesting question; and it is certain that the institution would be unwise to tardiness in practice, to be without arrangements for such assistance at once. The first was a model life-boat and carriage, as now adopted by the Institution, and stationed on many points of our coasts; the second, a boat, invented by Mr. Manby, which, one would imagine, was a model of which no improvement could be made; and Mr. Manby, 30 feet long, 7 feet wide, and 2 feet deep; it is considered to possess, in a high degree, seven qualities required in a life-boat—lateral stability, speed against a heavy sea; capability for landing on the beach; safety of discharge; and power of self-righting if upset, great strength, and storage-room for a number of passengers. Another specimen, was the life-boat which gained for Mr. Becoming, of Yarmouth, the prize of 200 guineas, in the Order of the Day of the French Government, and is better known than Mr. Peake's, but not quite so deep. A third was Mr. Palmer's life-boat, employed for many years by the Society, and stationed at many points on the coast. A
fourth was Mr. Ward Jackson's life-boat, such as is stationed at the West Harlpool Docks. Besides these boats there were several minor articles, such as travelling life-boat, to be used with the rocket and mortar apparatus; cork life-belts and life-boat, etc.; and so forth.

We have now reached the recent law concerning ship-wrecks. The year 1854 gave strength to the cause, by bringing the power of the government to bear upon it—not that such strengthening is necessarily a result; for the "right place, right time, and right person," nor do the government departments always do their utmost work at the right time; but it seems especially fitting that the legislature, and through it the executive, should have a voice in the shipping economy of a maritime nation. Mr. Cautley's Amendment, if it be properly handled, will do the necessary work. The Associate Board has been empowered to deal with the arrangements connected with the "Consolidate the Acts relating to Merchant Shipping;" it contemplates the Act 17 & 18 Vict. cap. 104, and received the royal assent August 10, 1854. The statute is of great length, and relates to eleven different topics, bearing upon the well-being of seamen and their ships; the relation of the Board of Trade to the Commercial Marine; the ownership, measurement, and register of British merchant ships; the qualifications of masters and seamen; the precautions and management of merchant ships, and the number and situation of pilots; the management and tolls of lighthouses; the constitution of the Mercantile Marine Fund; the laws relating to wrecks, casualties, and salvage; the liabilities of ship-owners; legal course of procedure in the event of misconduct on the part of owners or masters of merchant ships, and investigators in respect to wrecks and accidents, are to be appointed by the Board of Trade; new examinations for masters and mates are to be organised, separating foreign-going from home-trade passenger ships; the Board is empowered to IID. the necessary arrangements for the forecastle and storerooms, and mates, in case of misconduct or insufficiency; naval courts are to be instituted abroad or on the high seas, in correspondence with the Board, to inquire into cases of wreck, and report their findings; the boats to accompany all trading ships are denoted; every ship carrying more than ten passengers must be provided with a life-boat, or an ordinary boat rendered buoyant, and with two life-buys—the boat and buoys being always kept ready. In case of a life-boat being necessary, a man may be summoned by the Admiralty: iron steamers must have water-tight compartments, and safety-valves above or below the control of the engineer; sea-going ships must be provided with fire-engines and hoses, signals, guns, and ammunition for firing signals of distress.

Besides the provision for preventing wreck, the Act contains many clauses, applying to cases in which wreck may unhappily have occurred. As these arrangements are somewhat verbose, we may here quote a quarter of the Act, which may be considered as a specimen of the others:

"All matters relating to wreck are placed under the general superintendence of the Board of Trade, by whom 'Receivers of Wreck' are to be appointed. These receivers will have the charge of the coast and authority over all persons present at any wreck, or similar casualty, and power to issue such directions as may seem expedient for the preservation of life and property, or for the prevention of plunder and disorder. Whenever a ship is stranded, or otherwise in distress on British shores, bystanders are to be encouraged to render assistance, by having a pecuniary interest in the preservation of life or property. If services so rendered shall be instrumental towards the object in view, the persons shall have a claim on the owner of the ship for a 'reasonable amount,' and to ascertain what would be a 'reasonable amount' in each case; for enforcing the claim of the salvor against the disasters; for disposing of an unclaimed wreck; and for adding to the salvor's reward out of the Mercantile Marine Fund, in cases where life has been preserved, and where the wrecked ship is insufficient in value to pay the salvage awarded. The Mercantile Marine Fund here adverted to is made up in a curious way; it consists of certain fees received in connection with merchant-ships; lighthouse dues accruing by virtue of certain sections of the Act; rates accruing from lighthouse and ballastage in the Thames; and fees derived through the Bill of Wreck. The fund, kept with the aid of the Secretaries of the Board, and the payment of the salaries of examiners, surveyors, receivers, &c.; expenses in regard to lighthouses, buoys, beacons, lighthouse, ballastage, life-boats, &c.; and rewards to persons who assist in saving wrecked ships, or crews, or passengers. In pursuance of the powers conferred by the statute above sketched, the Board of Trade procured, early in 1855, to give effect to its provisions. Among other things, the Board addressed a circular to the Life-boat Committees throughout the United Kingdom. Considering that in 1854 no fewer than 1540 persons perished from wrecks on our own coasts, it is not too much to say that a wide field is yet open to the exertions of individual humanity and bravery. Doubtless, in many of these instances, there have been life-boats and willing aiders at the places where the calamities occurred. The principle intended by the Act, and entrusted to the Board of Trade for realisation, is not to induce the Board to interfere, but to bring all the assistance who will help themselves." A preparatory Circular was addressed to the several Life-boat Committees in September 1854, and this was followed by another in February 1855. The Circular dwelt strongly on the fact that the Board would insist on evidence of local activity before sanctioning grants out of the Mercantile Marine Fund. "In the wealthier and more populous portions of the kingdom, my Lords anticipate that the public spirit of the neighbourhood will promote the best result in reference to the Circular. In cases where a necessity for such assistance exists, the assistance contemplated by the Board of Trade will be confined to assisting towards the making and exercise of boats, and towards defraying expenses connected with actual service. The Circular is addressed to local Committees in correspondence with it, and they propose also to communicate from time to time with any Local Committee which may desire to address their communications directly to this department." The principal arrangements marked out in the Circular may be condensed as follows. Every Life-boat Committee must have as one of its members an officer of the Coast-guard, or of the Customs, or some official person connected with the Board of Trade. The Local Committee must be provided with a boat and boat-house satisfactory to the Board. The boats, house, and gear, must be kept in efficient repair, and accessible to the Inspector appointed by the Board. Each boat must have a coxswain, and a crew at least one-half more than is necessary to man the boat; permanent, if possible. The coxswain is to receive a small salary, and he, as well as the crew, are to receive certain specified rewards as payments for each time of exercising their duty. The Board of Trade is not intended to assist a wreck, and each time of undergoing special danger or fatigue. In the event of the death of any of the crew while on service, the Board will contribute towards a fund for the widow. All the payments are in the first instance to be made by the Local Committees, but to be accounted for by the Board of Trade when satisfactorily tested. Signal rockets and mortar apparatus on the coast are to remain under the charge of the coast-guard. The Life-boat Institution, to further the object held in view by the Board of Trade, also issued a Circular to the Local Life-boat Committees, containing advice and suggestions couched in more familiar language than a Government department is accustomed to employ. One extract will suffice to explain the principle of the Circular, and the care and skill which has been induced to tender their services in the hazardous duty of managing a life-boat. Speaking of the remuneration promised by the Board of Trade, the Circular says:—"The scale of payment for services in wreck cases has never before been paid, and is calculated to give every encouragement to seamen who engage in such an honourable and humane, yet often perilous, service. They conceive that the chief point in connection with it, which will call for the attention of the Committee, is the careful and discreet recommendation of the higher awards for extraordinary services; taking care never to do so but for those of a really distinguished character. The quarterly exercise of the life-boat should never be allowed. The Committee, as may be seen from the above extract, does not occur; the crew may still, with advantage, be exercised in rowing together, and the sound and tight condition of the boat herself, and the perfectness of her gear and
fittings ascertained; and if, from any cause, the greater part
of her ordinary crew are absent, she had nevertheless better
be taken aboard by any officer of the service into the port
who may be obtained, but always, if possible, in charge of the
permanent coxswain of the boat. The salary of the cox-
slain is double that which has previously been paid by this
institution. In return, it will be expected that they shall
devote the same amount to preserving the boats and
their appurtenances under their care in a constant state
of efficiency, and ready for instant service. With regard
to the hire of horses or steam-tugs, and the payment of persons
to assist in launching and hauling up life-boats, the attention
of the Local Committees will here be chiefly required to
check undue charges and to avoid incurring such expenses,
except when necessary. It is thought, also, that they may
do much good by endeavouring at all times to encourage
public spirit, and other disinterested motives, in those who
are called upon to assist on such occasions, and, as far as
possible, to devise such services of a meritorious character."
Under this Act, in 1857, the Board of Trade paid a total
sum of 6020l. for rewards, pensions, &c., and for maintaining
the Rocket and Mortar Apparatus.

SHIRE. See County Courts, S. 2, p. 156. Hundred
Courts and Courts Leet have long been almost entirely
obsolete, and the County Court statutes accordingly contain
provisions for the surrender of such courts by the lords
thereof to the Crown. It does not appear, however, that
any surrenders have yet been made.

Seminated silver; they are found near the surface, where the rock has undergone partial decomposition. The sulphur of lead, iron, and copper, of the mining regions, generally contain silver, and are also worked. (Dana.)

The principal mines of silver in Europe are those of Spain, of Kongeborg in Norway, of Saxony, the Hartz, Austria, and Russia.

In England, argentiferous galena is worked for its silver. Forty thousand tons of this ore were reduced in 1837, while contained upon an average about six ounces of silver in a ton of lead.

The annual product of the several countries of Europe is thus estimated by Dana in his Manual of Mineralogy:—

SIMCERE. [CAMARA, S. S.]

SIMETHIS; a genus of Plants belonging to the natural order Liliaceae, and the tribe Anthericaceae. The parts of the perianth are six, spreading, deciduous; the stamens are attached to the base of the perianth; the filaments bearded; the anthers incumbent; the capsules are 3-celled, and each cell contains two seeds.

*S. bicolor* is a recent addition to the British Flora. It is a native of the South of Europe, and is found on sandy heaths near the sea-shore. In England it was first found at Bournemouth, in Dorsetshire. It has also been found at Derry-noo, Kerry, in Ireland. This plant has linear leaves, flat, or a little keeled upwards. The flowers are panicked, the petals are purple without, and white within. In Hooker and Arnott’s ‘British Flora’ it is suggested that this plant may have been introduced with trees from France.

SIMIADIE. In the list of the specimens of *Mammalia* published by Dr. J. E. Gray, we find almost a complete representation of this family. They are as follows:—

SIPUNCULIDEA, an order of Echinodermata. Animals, embracing the families Sipunculidae, Priapulidae, and Terebellidae. This order is divided into three families: The cutaneous envelops are coriaceous, and free from calcareous corpuscles; there is no calcareous ring about the oesophagus; the body is cylindrical; the digestive canal runs asymmetrical.

1. The Sipunculidae (Syphon-Worms) have a retractile proboscis, the base of which is in the umbilicus, and round the extremity of which there is a circle of tentacles. This family embraces the genera Sprinea, Sipunculus, and Phazo-sclera.

Sipunculus (Bodachus) has a cylindrical proboscis shorter than the body, leaving a circle of short-fingered tentacles around its tip. In his 'History of British Star-Fishes,' Forbes refers three British species of Sipunculus of other authors to this genus—S. nudus, S. papillosus, and S. Harvetti. Sipunculus (Linnæus) has a cylindrical form about as long as the body, and a circle of simple linear tentacles around its tip. The following are British species of this genus—S. Bernardus, S. Johnstonei, S. saccasti, S. tenaci-setus, S. Forbesi, S. granulatus, S. punctatus, and S. Pallasi.

2. The Priapulidae (Tailed-Worms) have a retractile proboscis without tentacles, and the vent at the end of a long thread-like tail.

Priapulus (Lamarck) has the body truncated behind, and the proboscis truncated and pointed.

The only British species is P. caudatus, which is only rarely taken.

3. The Thalassemae (Spoon-Worms) have a body oval or oblong, with a long, fleshy appendage; vent at post-anterior extremity, tentacles none.

Thalassema (Cuvier) has a cylindrical body rounded and smooth behind; the proboscis retractile, short, furnished at one side with a long fleshy furrow—sole sheet, which is not retractile. T. Nepige (British species).

Echinurus (Cuvier) has a cylindrical body, set at its hinder extremity with circles of bony points, and a proboscis as in Thalassema. [Echinodermata; Thalassema] E. oxyurus is a British species.

and Analysis of the Peculiar Doctrines of the System of Political Economy founded by Ricardo. His most popular work was "The Diary of a Cudge" (1828), and his "Rambles and Recollections of an Indian Officer" (1843), a work which has been pronounced by competent authorities to be the best adapted of all existing treatises on British India, to give an Englishman a faithful picture of the actual state of the religious, social, and political conditions of the people of that country. He lived to see his measures with regard to Oude carried into effect by his successor, Sir James O ASTM, and to hear of the proclamation of Lord Dalhousie, announcing the annexation of the province of Oude, and the establishment of direct British rule.

Thoroughly rejected SMITH, as Dean of Stou, the his his work was obtained in England, with conspicuous success. He died in 1856, and was buried in the churchyard of Stou.

The theatrical enterprises of James Smith were chiefly associated with his paternal district. He carried on the work of improving the condition of the labouring classes, and of advancing the cause of religion and humanity by the suppression of Thuggee.

SMITI. [BROOKHAMSHIRE.]

SMELT. [SALMONDIN.]

SMILACIN. [CHEMIST, E. L.]

SMITH, JAMES, the great propagator of the system of deep ploughing and thorough draining, was born at Glasgow on the 3rd of January 1798. His father had been in business at Glasgow, and in which he acquired some property, but died when his son was only two months old, leaving him in the care of his grandfather, who was a day laborer in the country district of Carstoun in Stirling. After her husband's death Mrs. Smith resided with her brother, who was the manager of an extensive cotton manufactory at Deanston, a few miles from Stirling. Here he received his early education, and completing it at the University of Glasgow. On leaving the university he returned to his uncle, who had by the time removed to the Catrine Works in Ayrshire, where, in order to attain a thorough knowledge of the trade, he worked through the various grades, laboring with persevering industry for twelve hours a day, with such good effect that at eighteen he was entrusted with the entire management of the works at Deanston, into which he subsequently introduced many improvements in the process of the labourers. He was then discharged with the report by Mr. Chadwick, "A Report on the Sanitary Condition of the Labouring Population of Great Britain," published in 1841.

But Mr. Smith's attention had been early given to agricultural processes, and his intimate acquaintance with manufacturing machinery was made available in gratifying his predilection. The Dalkeith Farmers' Club having offered a prize of 500l. for a reaping-machine, Mr. Smith produced one, which, though it was not successful in obtaining the prize, it is said that he was requested by another to produce another in 1813. For this, though an accident prevented his gaining the prize, he received presents from several Scottish agricultural societies, and a gold medal from the Agricultural Society of Edinburgh. He had the management of his uncle's farm, and made such arrangements for improving the crops that his uncle's consent to carry out a full development of his theories. In 1823 however he became possessed of the farm of Deansston, about 200 acres of extremely poor land, having a soil not averaging more than four inches in depth, formed chiefly of the débris of the old red sandstone, with a subsoil partly of sandy clay and partly of a compact soil with stones, and the whole interspersed with boulder stones, producing little but rushes in the stately hollows and broon on the dry portions. The whole of this he intersected with drains, laid at distances of 31 feet and at a depth of 30 inches. This, and a subsoil plough to stir the ground deeply without bringing the subsoil to the surface, produced an effect on the crops that proved the soundness of his theory. In 1833 he published a pamphlet on "Thorong Draining and Deep Ploughing," which excited immediate attention among his more immediate neighbours, but it was several years before its merits were generally acknowledged and the practice it recommended was adopted.

In 1846 Mr. Smith was appointed one of a commission to inquire into the health and sanitary condition of our manufactories. One of his recommendations was the removal of the sewage for agricultural purposes; and he believed many difficulties to be overcome in effecting this, and Mr. Smith gave much attention to plans for overcoming them, proposing several means of singular mechanical ingenuity combined with simplicity. After considerable opposition an act of parliament was passed enabling municipalities to adopt his scheme where circumstances admitted of it. He also suggested several valuable improvements to the Agricultural Society of Edinburgh, and was a member, as he was also of the Glasgow Philosophical Society, to whose "Transactions" he was an occasional and valuable contributor. In political economy Mr. Smith was a follower of Adam Smith, and of course opposed to protection, holding that the increase of national wealth was the great end of government. After a life of almost incessant activity, he died on the 10th of June 1860, somewhat suddenly, having retired to bed on the 9th apparently suffering nothing but an accustomated feeling of weakness, which was not immediately removed. SMITH, JAMES, and HORACE, were the sons of Robert Smith, of London, an eminent legal practitioner and Solicitor to the Ordinance. James Smith was born Feb. 10, 1775, in London, where also Horace Smith was born in 1780. James Smith was engaged with his cousin, John Rev. Mr. Burford, at Chigwell, in Essex, was articled to his father, and in one year was taken into partnership. He eventually succeeded his father in the business and in the appointment of Solicitor to the Ordinance. Horace Smith became by profession a stockbroker.

The first literary productions of the two brothers were gratuitions contributions to "The Pic-Nic," a periodical started by Colonel Greville, in 1802. "The Pic-Nic" was soon merged in "The Cabinet," which maintained a stringing connexion till 1805. After that, "The London Review," of which Horace Smith was editor, was founded in 1817, and "The Quarterly Review," of which James Smith was editor, was started by Cumberland, the dramatist, on the principle of each writer affixing his name to his criticisms. James Smith wrote one of the articles, but the "London Re- view," after a coup with John Stuart, was disestablished and Horace Smith wrote several of the prefaces to a new edition of "Bell's British Theatre," which was published about this time under the sanction of Cumberland's name. They were also contributors from 1807 to 1810 to the "Monthly Mirror," in which they occasionally appeared. The poetical imitations entitled "Horace in London," which were subsequently published in a small volume. Horace Smith wrote several of these parodies, but the larger number were written by James Smith.

The London Review which the two brothers enjoyed arose chiefly from the "Rejected Addresses," a small volume which was published on the opening of the new Drury Lane Theatre, in October 1812. The committee of management had issued an advertisement requesting that addresses, one of which should be spoken on the first night, might be sent in by way of competition. As all the addresses sent in, except one, were to be rejected, Mr. Ward, secretary to the theatre, casually started the idea of publishing a series of these rejected addresses. The first edition appeared two days before the opening of the theatre. The brothers eagerly adopted the suggestion, and having immediately settled what authors each should imitate, Horace left London on a visit to Cheltenham, and James remained at home. Horace having succeeded in making a selection of very eminent writers, sent the manuscripts of the rejected addresses two days before the opening of the theatre. Each then submitted his productions to the other; a few verbal alterations were made, a few lines were added, and the little book was immediately printed and published. It was received by the public with enthusiastic delight. As the "Rejected Addresses" are humorous imitations mostly of authors well known, and as the work is still in circulation, it is perhaps worth while to mention that the imitations of Wordsworth ("Baby's Dobe"), Cobett ("Hampshire Farmer's Address"), Southey ("The Rebuilding"), Coleridge ("Premonial Hasting"), and Crabbe ("The Theatre"), are by James Smith, as well as the scenes styled "Drury Lane Hasting," the "Theatrical Alarm Bell" (an imitiation of "The Alarm Bell"), and the passage of the "Swallows" "Meschet," "George Barnwell," and "The Stranger." The rest of the imitations are by Horace Smith. The copyright, which was originally offered to Mr. Murray for 200l., was purchased by him in 1819, after the sixteenth edition, for 1l. 1s. 4d.

Besides a great number of amusing trifles which James Smith contributed to the periodical literature of the day, he was a gratuitions contributor to the earlier series of theatrical entertainments entitled "At Home," in which the older dramatists were published together with many original pieces of humorous imitation. Subsequently, for the "County Cousins," the "Trips to Paris," "Air-Ballooning," and the "Trip to America," he received from Mr. Mathews altogether 1000l. "You are the only man in London," said Mathews to James Smith, "who can write what was, good nonsense."
The brothers were both admired for their conversational powers. James Smith especially had a large circle of acquaintance, and went much into society. Though he was always a man of temperate habits, he became in middle life subject to attacks of gout, which increased in frequency and severity till he gradually lost the use of his limbs, and could only move himself by the aid of crutches. He died in London, December 34, 1836. In early and middle life he was distinguished mainly beauty both of figure and face. He was never married.

Horace Smith contributed numerous pieces of poetry, half playful, half sentimental, to the 'New Monthly Magazine,' while it was under the editorship of Thomas Campbell, the poet, and also several of the Holy Scriptures and some of the New Testament, published in 1835. In the twenty-third year of his 'Life and Mission,' 1846, was the latest. In the intermediate twenty years he gave the public 'Brumelhote Home,' 'Terror Hill,' 'Reuben Apley,' 'Zella,' 'New Forest,' 'Walter Colyton,' 'Jane Lomax,' 'The Moneyed Man,' 'Adam Brown,' 'Artur Arnold,' and others. Horace Smith died July 13, 1849, at Tunbridge Wells. He was a widower, and left two daughters.

(System, Letters, and Comic Miscellanies in Prose and Verse, by the late James Smith, Esq., one of the authors of the 'Monthly Magazine,' dedicated to his brother, Horace Smith, Esq., 3 vols., cr. 8vo, 1840.)

SMITH, JOHN PYE, D.D., LL.D., one of the most learned ministers and theological tutors of the Independent or Nonconformist denomination in Great Britain. He was born in the town of Homerton, in the parish of Hackney, London, on May 29, 1774. In his early years he was employed in the shop of his father, who carried on a respectable bookselling establishment in Sheffield; but always a diligent student, and becoming strongly impressed with religious feelings, he became desirous of entering upon a ministerial career; accordingly left business, and in his twenty-second year entered the Independent Academy at Rochester. Here he devoted himself zealously to the studies of the place, and such was the character he attained for ability and learning that, on a vacancy taking place in the Homerton Independent Theological Academy, Mr. Smith was chosen in 1800 to occupy the post of classical tutor in that seminary. At Homerton he subsequently formed a church, of which he became pastor, and which increased so largely in numbers as to require a separate chapel. In 1807 he received the diploma of D.D. from Yale College, Newhaven, Connecticut. In 1813 Dr. Pye Smith gave up the situation of resident classical tutor, retaining at the request of the directors the post of divinity tutor. In 1817 he was elected as a trustee of the College, Aberdeen. Dr. Smith became again in 1843 the resident tutor at Homerton, which office he filled till the breaking up of the establishment in 1850, when New College, St. John's Wood, was formed from the juncture of Homerton, Macclesfield, Manchester, and Chesham. He had been for many years afflicted with deafness, then retired from active duty, and his friends and admirers testified their regard for his character by raising a sum of 3000l. to provide an annuity for him while he lived, the interest to be afterwards devoted to the foundation of a Smith scholarship in New College. Dr. Pye Smith died on February 6, 1861, in his seventy-seventh year. Dr. Pye Smith was held in unusual regard by all who knew him, as much for the singularly happy subject matter of his life, as for his earnestness and devotion in his official duties, and his extensive erudition. He had been twice married.

Dr. Smith was a man of uniting industry, as well as of very unusual acquirements. He published numerous works on theological subjects; and especially the science of geology. His great work was 'The Scripture Testimony to the Mosaic,' 2 vols., 1818 and 1821. The remarkable range of reading which this work displayed, and particularly its familiarity with modern geographical research, and with the attainments of English divines, and especially with those of the Nonconformist body, attracted great attention to the work, and though some of the positions of the author were regarded as questionable by many theologians who agreed with him about the inspired origin of the books of the Bible, he was considered a high place, and eventually came to be pretty generally regarded as a standard work on the subject of the divinity of Christ, and as perhaps the most important work of the kind on the orthodox side of the question. In subsequent edi-

tions the work was in parts considerably enlarged, and in some respects modified; and in its final shape it may be regarded as embodying almost the whole of the erudition on the important subject of which it treats. The fourth edition was published in 1847. It was in the middle of which were a controversial character, may be summarized—'The Adoration of our Lord Jesus Christ vindicated from the Charge of Idolatry, a Sermon,' 1811. 'Four Discourses on Natural and Practical Science,' third edition, 1847. On the Personality and Divinity of the Holy Spirit, a Sermon,' 1831. 'The Mosaic account of the Creation and the Deluge, illustrated by the Discoveries of Modern Science,' fourth edition, 1848. Dr. Pye Smith was a Fellow of the Royal Society and of the Geological Society, and took a deep interest in the philanthropic and religious movements of the day.

SMITH, JOSEPH, founder of the religious body commonly known as Mormons, but called by their founder and by themselves 'The Church of Jesus Christ of Latter Day Saints.'

Whether regarded as a religious, political, social, or intellectual phenomenon, the rise and progress of Mormonism is one of the most remarkable movements of modern times; and a calm survey of its origin and development, made with a view to arrive at a true knowledge of the facts, and, as far as practicable, to comprehend, that is, like the system and its effects, the character of its founders, and its influence on its disciples—could not but be serviceable as well as interesting. Such a comprehensive statement as that which will be attempted in the present article will be to give a sketch of the founder of Mormonism, and of the system as he left it. Its subsequent development and present state will be noticed under Utah, S. 2.

Joseph Smith published an autobiography; and a strange book purporting to be written by his mother has been published, under the title of 'Biographical Sketches of Joseph Smith, the Prophet, and His Progenitors for many Generations, by Lucy Smith, Mother of the Prophet.' Of these, as well as the notices of him by his adherents and opponents who profess to have obtained their information respecting him at first hand, we have made use; but we prefer to let the Prophet in a measure tell his own story as we find it in a short sketch of himself and his system, which he supplied a few months before his death to Mr. Daniel Rupp for that gentleman's 'Original History of the Religions Denominations at present existing in the United States,' 5vo, Philadelphia, 1844, and which may consequently be considered as an extract from the autobiography of what Smith himself wished to be believed.

He says—

"I was born in the town of Sharon, Windsor County, Vermont, on the 23rd of December, 1805. When ten years old, my parents removed to Palmyra, New York, where we resided about nine years. Among this number was a man named James, who had confidences in the declaration of James, 'If any man lack wisdom let him ask of God, who giveth to all men liberally and upbraideth not, and it shall be given him.'

"I retired to a secret place in a grove, and began to call upon the Lord. While fervently calling upon the Lord, my mind was taken away from the objects with which I was surrounded, and I was transported in a heavenly vision, and saw two glorious personages, who exactly resembled each other in dress and feature, and who were in the air, as if they had entered which eclipsed the sun at noonday. They told me that all the religious sects were believing in incorrect doctrines, and that none of them was acknowledged of God as his Church and Kingdom. And I was expressly commanded to 'go not after them,' at the same time receiving a promise that the fulness of the Gospel should at some future time be made known to me."

This "fulness of the Gospel," was that revealed in the Book of Mormon; and as his account of the discovery of the
book and its contents is really the point on which our estimate of it, and the doctrine must to a great extent turn, it will be best given in its own words and without abridgment. He says:—":On the evening of the 21st of September, A.D. 1823, while I was praying unto God and endeavoring to exercise faith in the promises of Solomon, and was engaged in prayer, it suddenly flashed into my mind, that I was surrounded by purer and more glorious appearance and brightness, burst into the room; indeed, the first sight was as though the house was filled with consuming fire. The appearance produced a shock that affected the whole body, and was at the same time, a personage stood before me, surrounded with a glory yet greater than that with which I was already surrounded. The messenger proclaimed himself as an angel of God, to bring to the joyful tidings, that the covenant which God had made with the Jaredites, was at hand to be fulfilled, and the preparatory work for the second coming of the Messiah was speedily to commence; that the time was at hand for the Gospel in all its fulness to be preached in power unto all nations, that a people might be prepared for the Millennial reign.

"I was informed also concerning the aboriginal inhabitants of this country (America) and shown who they were, and from whence they came;—a brief sketch of their origin, progress, civilization, language, government, and form of society, with a prospect of their future and the blessings of God being finally withdrawn from them as a people, was made known unto me. I also was told where there were deposited some plates, on which was engraved an abridgment of the records of the ancient Jaredites, which existed in the temple of Solomon. The angel appeared to me three times the same night, and unfolded the same things. After having received many visits from the angels of God, unfolding the majesty and glory of the events that should transpire in the last days, on that morning of the 22nd of September, 1823, the angel of the Lord delivered the records into my hands.

"These records were engraved on plates which had the appearance of gold; each plate was six inches wide and eight inches in height; they were not quite square. They were filled with engravings in Egyptian characters, and bound together in a volume, as the leaves of a book, with three rings running through the whole. The volume was something near six inches in thickness, a part of which was sealed. The characters on the unsealed part were small and beautifully engraved. The whole book exhibited many marks of antiquity in its construction, and much skill in the art of engraving. With the records was found a curious instrument which the ancients called 'Urim and Thummim,' with the following inscription in that language: a bow fastened to a breastplate. Through the medium of the Urim and Thummim I translated the record by the gift and power of God.

"The most convenient and interesting book of the history of ancient America is unfolded from its first settlement by a colony that came from the tower of Babel, at the confusion of languages, to the beginning of the 5th century of the Christian era.

"We are informed by these records, that America, in ancient times, has been inhabited by two distinct races of people. The first were called Jaredites, and came directly from the tower of Babel, about 600 years before Christ. They were principally Israelites of the descendants of Joseph. The Jaredites were destroyed about the time that the Israelites came from Jerusalem, who succeeded them in the inheritance of the country. The principal nation of the Jaredites is said to have been the 4th millennium of the 4th century. This book also tells us that our Saviour made his appearance upon this continent after his resurrection; that they had apostles, prophets, pastors, teachers, and evangelists; the same order, the same priesthood, the same ordinances, gifts, and blessings, as was enjoined upon the eastern continent; that the people were cut off in consequence of their transgressions; that the last of the prophets who existed among them was commanded to write an abridgment of the prophetic history, that had existed on this continent, for the earth, and that it should come forth and be united with the Bible, for the accomplishment of the purposes of God in the last days. For a more particular account I would refer to the Book of Mormon.

"While I was thus considered, the Prophet's narrative. It will have been noticed that the account of his early life, and of his proceedings between the first appearance of the angel and the discovery of the plates, is remarkably vague. His education had evidently been of the rudest kind. From various accounts, including those of his mother, it would seem that he used to assist his father in his business, but that he was of an unsettled disposition, and probably spent a good deal of time in wandering about the country. It is stated that he was induced to the pursuit of learning by trying for mineral veins by a divining-rod, and some affirm that, like Sidrophel, he used "the devil's looking-glass—a stone," and was consulted as to the discovery of gold. It is said that he was familiarly known as the "money-digger," and on one occasion he had been, at the instigation of a disappointed client, imprisoned as a vagabond. He is also stated to have carried off and married a Miss Hales, during the interval between the first angelic visitation and his introduction to the Urim and Thummim."

"As to the Book of Mormon itself, the authorship has been claimed for one Solomon Spalding, a Presbyterian preacher, who having fallen into poverty composed a religious romance, entitled 'The Manuscript Found,' which professed to be a narrative of the migration of the Lost Tribes of Israel from Jerusalem to America, and their subsequent adventures on that continent, in the hope of obtaining enough from its publication to release him from his difficulties. The work was not completed at the time of the author's death; but ten years after his death, the manuscript was carried by his widow into New York, where it was stolen by or somehow got into the hands of Smith, or Rigdon (an early associate in his proceedings). The statement is supported by affidavits from James Hargrave, Robert Hales, and some other persons, who declare that they had heard him read portions of the work which were substantially the same as parts of the Book of Mormon. The story is incoherent in its details and the authenticity of the affidavits does not seem clear; but the work itself appears to be very well with such an origin, supposing, that is, that the Presbyterian preacher, as might well have been the case, was a rude-minded uneducated man, sufficiently familiar with the history of the United States and with the time of the Mormonites, and who, in writing this romance, employed a knowledge of the tongue, and made use of the easily-obtained information respecting the ruins of ancient 'towns and temples,' which have been discovered in various parts of America, as a groundwork for his narrative. The book itself is (even now that its gross grammatical errors are said to have been expunged) a singularly ill-written one, and how any decently-educated man could have written it as a book to be read for amusement would be inconceivable, were it not that experience teaches us that authors are by no means always in good faith. There is also, in this work, as there is certainly nothing in the book to contradict the supposition that it is the work of Smith himself—for as to its being a divine revelation, the most cursory examination of it will demonstrate its utter improbability of that, if its possibility were otherwise conceivable. Be the author who he may, Smith having obtained the book—whether from Solomon Spalding's travelling chest, his own brain, or the stone-box which the angel discovered to him—thought it behoved him to conceal his treasure known. At first he told the members of his own and his father's household, and, more fortunately than Mahomet, found little difficulty in persuading them of the truth of his mission and the reality of the gift. But he says:—"As soon as the news of this discovery was made known, false reports, misrepresentation, and slander flew, as on the wings of the wind, in every direction. My house was frequently beset by mobs and evil-designing persons; several attempts were made to destroy the book, and the device was made use of to get the plates away from me; but the power and blessing of God attended me, and several began to believe my testimony."

"Among those whom he told of the discovery was a far named Hare, whom he persuaded to convert his stock in money into order to assist in printing the book. But Harris wanted to consult some scholar, and Smith was induced to entrust him with a copy of a portion of one of the golden plates together with a statement of the facts as related by Anthon, who according to the triumphant declaration of the Mormonites, was unable to make out the characters, which he described to be "reformed Egyptian"—and this is one of the proofs cited by Mormonite teachers of the authenticity of the book. Dr. Anthon's family is different. He says that he at first supposed the paper to be a hoax, and gave little heed to it; but on hearing the man's
story, he assured him that the work was an imposture, and strongly advised him not to have anything to do with it. The paper itself he thus describes (and it is the only description of the "Book of Mormon" which has been published), in fact, that its appearance consisted of all kinds of fiction, characters, disposed in columns, and had evidently been prepared by some person who had before him, at the time, a book containing various alphabets. Greek and Hebrew letters, crosses and flourishes, Roman numerals, and, from that time, a most astonishing rapidity, and churches were soon formed in the states of New York, Pennsylvania, Ohio, Indiana, Illinois, and Missouri. In the last-named state a considerable settlement was formed in Jackson county; numbers joined the church, and we were increasing rapidly. We had made land and had given our farms teemed with plenty, and peace and happiness were enjoyed in our domestic circle and throughout our neighborhood; but as we could not associate with our neighbors who were members of the basest of men, and had fled from the face of civilization society to escape the hands of justice—in their saith-break, horse-racing, they commenced at first to ridicule, then to persecute, and finally organized mobs and burned our houses. We were whipped many of our brethren [Smith himself was tarred and feathered], and finally drove them from their habitations; there, houseless and homeless, contrary to law, justice, and humanity, had to wander on the bleak prairies till the children left their mother. The date of this event is the month of November (1833)."

The government, he says, winked at these proceedings, and "the result was, that a great many of them died; many children were left orphans; widows, widows, and husbands, widowed in the very act of possession of the mob, many thousands of cattle, sheep, hogs, and crows; and in the household, store goods, and printing-presses were broken, taken, or otherwise destroyed. These outrages proceeded in a manner which the more scandalous practices of the Mormonites—practices almost perfectly analogous to those formerly charged upon the Anabaptists and other new sects, and in all probability with no more foundation in truth. Driven from Jackson, the Mormonites settled in Clay county, where they remained three years, when being again threatened with violence, they removed to Caldwell and Davies counties. Here their numbers rapidly increased. They formed three extensive settlements, established a bank, and appeared to be in a most flourishing condition. But again various troubles fell upon them. The bank failed, and Smith was obliged to conceal himself. Their old persecutors roused the popular feeling against them, and finally, by an extraordinary order, issued by the governor of Missouri, the Mormonites were ejected from their homes, plundered of their goods, and rejected, the women especially, to the most frightful attentions. Being thus expelled from Missouri, they settled in Illinois, where they lived to the very last with great kindness. An admirable site having been purchased by them on the Mississippi, at the head of the Des Moines Rapid; they "in the fall of 1839" laid the foundations of their famous city of Nauvoo, or 'the Beautiful,' for which the state legislature granted them in December 1840 a charter of incorporation with usual privileges. Smith dwells with great delight on this city, which he had seen rise up under his presidency from a wild tract to be a place of 1,500 well-built houses, and more than 15,000 inhabitants; all looking to him for temporal as well as spiritual blessings. Those things which he describes as provided for, was "the University of Nauvoo, where all the arts and sciences will grow with the growth, and strengthen with the strength of this beloved city of the saints of God. The grand feature of this city is the great temple, which Smith thus describes:—"The temple of God, now in the course of erection, being already raised one story, and which is 120 feet by 60 feet, of stone with polished pilasters, of an entire new order of columns, surmounted by the most perfect specimen of the temple of Solomon. The materials of worship of God, as well as unique wonder of the world, it being built by the direct revelation of Jesus Christ for the salvation of the living and the dead."

The progress of Nauvoo was even more rapid than that of any of the other settlements. It was crowded in from foreign countries as well as from different parts of America; the people were peaceful and industrious, the land was fertile, and the settlement was eminently prosperous. Dangers of...
various kinds beast Smith, but he escaped from them all. He had in 1841 been arrested on a charge of sedition, &c., but being carried before the authorities of Nauvoo, he was set at liberty. Smith was chosen as the first governor of the new city, ex-governor of Missouri, and he deemed it prudent to conceal himself for a time, but eventually surrendered, and being able to prove that he was "some hundreds of miles distant" from the scene of the attack, he was acquitted. Among the consequences there were some.createous and perilous, but they never extended widely, and were easily suppressed. With the 'gentiles' settled in Nauvoo, and whom he could not keep out, he had more trouble; and, as might have been expected, they had had little to do with the revolution of the Mormons from their former cities followed them here, and suspicion and hatred gathered about them. But Smith from the foundation of Nauvoo had been making provision against this danger. He had procured the inns, as a priest, and the latter effecting the formation of an independent civil militia, which he at once organised, and of which he constituted himself 'lieutenant-general.' He also set about consolidating his spiritual as well as civil government, and he made careful provision for an ample succession of heirs and zealous missionaries. The Book of Mormon was an historical revelation: the doctrine and discipline of the church were to be enunciated in subsequent revelations as circumstances called them forth. For the first time, therefore, a sacred book, seemingly revelation. In other words, this 'church of the latter days' was to be a theocracy, with himself as its head and inspired legislator—at once the Moses and Aaron of this new house of Israel. Nor in this capacity was he ever found wanting. He was able to the monarch of men's hearts with his needful revelation. In this manner he successively defined his own position, provided for his requirements, established his 'orders' of apostles, elders, priests, &c., in the church, and regulated all ceremonies, as well as defined its doctrines. These later revelations will all be found in the 'Doctrines and Covenants of the Church of Jesus Christ of Latter-Day Saints, selected from the Revelations of God, by Joseph Smith, President, of which there have been numerous.editings since the first appearance of the new order. However well his followers, he was sadly deficient in wariness in his dealings with the outer world. Again and again he suffered himself to come into contact with the civil authority of the state; and his impolicy led him, notwithstanding the terrible lessons he had already received, to defy the storm that was plainly gathering around him. So little did he heed the danger, that in prospect of the presidential election of 1844 he published his own 'Views of Government,' a sort of social sociology, and laid the foundations of a brotherhood, were declared to be the motive forces of just government: and he was actually put in nomination for the presidency.

But he did not live to the day of election. The storm that had been so long gathering, burst before then and swept him away in its fury. The 'gentile' residents in Nauvoo, supported as it would appear by some of the dissatised among the saints, had established an opposition newspaper, 'The Expositor,' which growing more and more bold, ventured at length to denounce the morals of the prophet as well as his system of government. The city council now interfered and condemned the newspaper to silence; upon which a mob assembled, broke into the office and destroyed the presses. The mayor and the Mormon leaders with inciting the mob to this act, and they were formally arrested, but immediately sat at liberty by the public prosecutor entering a bill of complaint, a process said to have been forced as a threat, and charged with any offense. The injured parties now carried their complaints before the governor of Illinois, who, having been long waiting, as is said, for a legal opportunity to crush the power of Smith, readily granted a warrant for his apprehension, June 34th, 1844. This is the story of his arrest, and the impulse was to put Nauvoo into a state of defence, and his militia was drawn out. But on the approach of the state troops, he offered, in order to avoid bloodshed, to surrender on condition that Governor Ford would guarantee his safety till his trial. The governor consented to this, and Smith, his brother Hyram, and some of the other leading members of the council were carried prisoners to Carthage jail. A guard small in number and purposely chosen, from among Smith's declared enemies, was set over them; but, on the 27th of June, a mob of about 200 armed ruffians broke into the jail, and firing in at the door of the room in which the brothers were confined, shot Hyram dead at once. Joseph Smith attempted to escape by the window, was knocked down, cut out, and, though his dying exclamation was said to have been "O Lord my God!" His body was given up to his friends, and buried with great solemnity.

Perhaps the death of Smith at that time did more than any other fact to cause the most conspicuous steps to be taken, to confirm and consolidate the Mormon church. Smith himself, it is evident, was becoming intoxicated with power and prosperity. He is said to have given way to lust and intemperance, and though the statement is without sufficient proof, it appears that in the report, though the extent has been no doubt greatly magnified. There is every reason to believe that he was beginning to distrust even his followers, when his murder banished all feelings but those of pity and reverence. Therefore, he was thought of only as the glorified deceased; and his followers braced their nerves to endurance by the remembrance of their master's fate and example. In Nauvoo itself the impression produced by the events was most profound. At first the popular cry was only for revenge, but their leaders exhorted them to forbearance, and succeeded in their exhortations. They then proceeded to elect a successor to Smith. Three candidates put forward their claims to the prophet's place. The choice of the council fell on Brigham Young, and his followers were ready to remove his people far beyond the farthest settlements of his countrymen, convinced now that only in a country far distant from societies living under the established forms, could the vision of the Prophet stand a chance of realization. The want of a man was not the only defect that was to be remedied. They should be un molested till they could finish and dedicate their beautiful temple; and as soon as that was accomplished, September 1844, the last band of the brethren departed from the land of their hopes to seek a new land of promise.

Shortly before Smith's death he estimated his followers at upwards of 150,000, and declared that they were to be found among almost every civilised people on the face of the earth, and that he with his sons and nephews, would proceed to the diffusion of his discipies, but that their number was very great, and that they were very widely spread, there can be little doubt. To what extent, if any, they have since increased, we need not now stay to inquire. Their present condition will be more properly noticed in another article [Utah, S. B.]. It only remains now to state their doctrines as enunciated by Smith, and this will be best done in the creed which he forwarded a few months before his death for publication under the name of the 'Latter-Day Saints'有什么意义，其目的是什么？
according to the dictates of our conscience, unmolested, and all
allowed men the same privilege, let them worship how,
where, or what they may.
We believe, being subject to kings, presidents, rulers, and
and, in obeying, honouring, and sustaining the
law.

"We believe in being honest, true, chaste, benevolent,
and in doing good to all men: indeed we may say
that a large proportion of the world's greatest
things, 'we hope all things,' we have endured very many
things, and hope to be able to endure all things. If there
is anything virtuous, lovely, or of good report, or praiseworthy,
within their

In this respect it will be seen that there is no reference to
what is now commonly regarded as the characteristic feature
of the Mormon system—polygamy, nor has it been mentioned
in connection with Smith himself. There is no doubt that
during the absence of the Prophet, and of his followers, the
charges brought against the Mormons, but the doctrine of
a plurality of wives was never openly taught until after his
death, and if he proclaimed it at all, he confined the revela-
tion to the initiated. He is said however to have "sealed"
to himself "plural wives," as the Mormon expresses it, about
two years before his death; and the privilege may have
been accorded to some of the chief of his followers. But the
doctrine in its present form is one of the developments
of the

SMITH, ADMIRAL SIR SIDNEY, was born at West-
minster in 1765, and in his twelfth year was sent as a
midshipman on board the Sandwich, Lord Rodney. At
the age of sixteen he was made lieutenant, and at nineteen post-
captain. In 1784, he was commissioned in the Swedish
fleet, and landed at Copenhagen. In 1785, he
obtained permission to offer himself as a volun-
teer to the Swedish legislature, in whose service he showed so
much

able to his investment with the order of
the sword. On the surrender of Toulon to Lord Hood,
August 1793, Captain Smith, being in the south of Europe,
unemployed, hastened thither, and offered his services, which
were accepted; and on the evacuation of the city in the
following December, the destruction of the French ships of
war, which could not be removed, and that of the powder
 magazines, was one of the most celebrated and dangerous
attempts ever attempted by him. On his return to
England he was appointed to the command of the
Diamond, with a small flotilla, charged to cruise in the
Channel. He succeeded in considerably annoying the enemy,
but in attempting to cut out a ship at Harre he was
made prisoner.

After a confinement of over two years, Captain Smith, by
the assistance of a French officer named Philippeau, made
his escape and reached England in safety. Appointed to
the command of the sloop, 60 guns, he returned to
Smyth proceeded to Constantinople, and thence to Acre,
which, as the key of Syria, was then closely invested by
Bonaparte at the head of 10,000 men. Sir Sidney, with
admirable decision and promptitude, brought two of his large
crudes to the assistance of the French, and
the same time sending his friend Colonel Philip-
peau, who was a skilful engineer, to assist in directing
the fortifications; Bonaparte made several desperate assaults
upons the place, but was on each occasion repulsed with
heavy loss, and ultimately was compelled to raise the siege
and retreat in disorder. This successful resistance was
attributed in no small degree to the gallantry and energy of
Sir Sidney Smith. In the events which followed Bonaparte's
decisive victory in 1797, Sir Sidney, with admirable
judgment, promptly chose the moment when General Kleber on whom the command of the French
army had devolved, offered to evacuate Egypt, Sir Sidney,
though without instructions, confirmed the treaty which he
made with the Turkish commander to that effect at El-Arish,
January 24, 1800. The English ministry however disapproved
his procedure, and Sir Sidney continued to participate in the
measures adopted for the expulsion of the French. In
the battle of Alexandria, in which Abercrombie was killed, Smith
was one of the heroes of the battle, and was designated
'Hero of Acre,' as he was popularly designated, was received
with great enthusiasm, and among other marks of public
approval, had the freedom of the city of London voted
along with the present of a valuable

SMITH, B.A., Lecturer, and during the
brief peace took part in the debates; but on the renewal of
war he was appointed to the Antelope, 60 guns, with
command of a flying squadron, at the head of which he displayed
his wonted activity. In 1804 he was made colonel of
marines; in 1805 rear-admiral of the blue; and in 1806
he proceeded to the Mediterranean in the Pompey, 80 guns,
with a small squadron to harass the French in Naples. He
was ordered to capture Corfu, succeeded in twice throwing succours into Gaeta, landed his men, and burned and destroyed the
battering ships of war and turned gun-boats. In 1810 he
was made vice-admiral: in 1819 he was appointed second
in command of the Mediterranean Fleet, and remained stationed
in comparative inactivity off Toulon to the end of the
war, when he was knighted K.C.B., and received a pension of
1000l. for his distinguished services. In 1821 he rose to
the rank of full admiral, and in 1830 succeeded King William IV.
as lieutenant-general of marines. He died May 26, 1841, at
Paiia, where, in consequence of pecuniary difficulties arising
out of unsuccessful trading speculations, he had been for
some years a resident.

SMYTH, WILLIAM, was born at Liverpool in 1766,
and was educated at Peterhouse, Cambridge, where he graduated
B.A., and 8th Wrangler in 1797, and M.A. in 1799. His
father, who had saved the property of his family as a
consequence of the war between England and France in
1793, he was compelled to look around for means of main-
taining himself, and accepted the office of teacher to
Thomas, the eldest son of a wealthy gentleman in
Shropshire. Of his connection with these two celebrated characters Mr. Smyth has left an interesting little 'Memoir,' printed not for sale in 1840. Mr.
Smyth had accompanied his pupil to Cambridge, and from
that time it became his settled residence. In 1806 he pub-
lished a small volume of poetry, the fourth edition of
which was issued in 1830. In 1808 he was appointed
Professor of Modern History, which secured him a moderate
income, as the salary is 400l. a year. He commenced
his lectures the same year, of which the first series comprised
two years; during that period he added to the study of the
northern nations and the

Orchelis has only a few rays covered with spine-bearing
4 N 2
wants; the intermediate spaces porous; the avenues bordered by two sets of spines.

There are two species which are not uncommon on the shores of the British Islands, C. oculata and C. rosse. Solaster (Forbes) has many rays studded with knobs of spines; the avenues bordered by three sets of spines.

S. pappos, the Rosy Sun-Star, is common on the eastern coasts of Great Britain, where, on account of the number of its rays, it is called Teu-Fingers. It is of a deep red or coppery hue. It is a British species in S. endeca.

SOLDANella, a genus of plants belonging to the natural order Primulaceae. Some of the species are slightly purgative.

SOL DUTT. [WARWICKSHIRE.]

SOLITARY BIRD. [DNS.]

SOLON'S SEAL, the common name of the genus Polygonum, a genus of Plants belonging to the natural order Liliaceae, and the sub-order Asparagaceae.

Polygonum has the perianth tubular, 6-toothed, tardily deciduous; the ovary 3-celled; 3 styles ovulate; the stigma blunt, trigonous; berry with 1-seeded cells; the flowers not jointed to pedicel. There are three British species.

P. sericefolium has lanceolate shaped leaves, with an erect plait; is last placed of Grass at last. P. officinarum. Solomon's Seal, has leaves ovate-oblong, half-cloping, glabrous, stem angular; peduncles 1-2-flowered; filaments glabrous. It is the ConsolidaPolygonum of Linnæus, and is known as a man abundant, which is confounded with the following. It is only found in Scotland.

P. multiflorum has leaves ovate-oblong, half-cloping, glabrous, alternate; stem round; peduncles one or many-flowered; filaments downy. This plant is the common species of Solomon's Seal.

SOMERVILLE T. [MINERALOGY, S. 1.]

SOMMITE. [NAPOLITAN.]

SOPHIA, a lady in Belgium in European Turkey, situated on the route from Constantinople to Belgrade, about midway between Nice and Philippopolis, near the point indicated by 42° 37' N. lat., 22° 27' E. long., in a wide plain bounded by high ramifications of the Balkan, and traversed by the Iaca, a feeder of the Danube, and has about 10,000 inhabitants, the greater part of whom are Christians. It is a large place, and has a beautiful appearance from a distance, but the streets are narrow, tortuous, dirty, and lined by high mud walls, which here and there inclose good houses, but in general the houses are poorly built. It has a great number of mosques and Christian churches, which are the principal buildings in the city; there are also a large and well-frequented bazaar, public baths (which are supplied from a hot-spring), and khans. The chief industrial products are—knitted-stockings, for which the place is celebrated, hair-cloth, aniline-dyes, leather, and tobacco. Sophia was formerly the residence of a pasha and capital of an eyal of the same name, but the eyal is now named from its capital, Nissa, called by the Turks, Tsipetje. It gives title to a Greek archbishop and to a Catholic bishop, the archbishopates are honorary, the Catholic is synodal. Sophia is a place of considerable commerce. It was founded by the emperor Justinian on the site of the ancient Sardica. The only remains of antiquity are the ruins of the church founded by Justinian. Sardica is famous for the council held in it A.D. 347, which confirmed the decrees of the Pope acquitting St. Athanasius of the charges brought against him at the council of Antioch. The council of Sardica also passed twenty canons, one of which permits a bishop condemned by a general council to be restored to his bishopric. The archbishops, to the number of about eighty, withdrew from the council of Sardica to the town of Philippopolis, and held what they called the council of Sardica, in which they pronounced sentence of excommunication against Otius, St. Athanasius, and the Pope. (Frontier Lands of the Christians and Turk; L'Art de Veiyir le Dots.)

led the attack of the left at the battle of Weissenaerberg, and repulsed a body of Austrians. His next service was in the Palatinate under General Lefebvre, whom he contrived to be removed by the post of chief of the guard. In 1794 Soult was created colonel, and was one of the most distinguished officers present at the great battle of Fléron, June 26. He displayed great skill by his dispositions in this action, and in the subsequent fighting at Darmstadt. After the battle Soult, having been wounded, was taken prisoner by the Prussians and returned as prisoner of war. He was exchanged, however, and despatched to the troops of Napoleon himself, for whom he continued to serve, and in 1807 was appointed to the staff of Napoleon, and made Chief of Staff. Soult served in the battle of Austerlitz, December 2, and, being so efficient, Napoleon thanked him on the 29th of December, and made him one of the first of living strategists. Thenceforward, and until the end of the war, he was ranked as one of the leading generals of France, to whom the greatest undertakings might be committed when Napoleon himself was elsewhere. With the fall of Napoleon, Soult retired from the active service, and after the battle of Eylau, February 8, 1807. After the battle of Jena, October 14, 1806, he defeated Marshal Kalkreuth, captured Magdeburg, and put to flight the Prussian General Bliicher and the Russian General Lestocq. Again he signalled himself at the battle of Eylau, February 6, 1807, and captured Königsberg the same year.

He had now been fifteen years in constant service in the field, and had fought under the ablest and most experienced commanders, with all of whom he had enjoyed the same confidence. He fell, however, out of grace with Napoleon, and, finding that the Marshal of Spain was not in favor, he retired to his villa on the Morvan, and much to the advantage of his health. In 1809, Napoleon, seeing the risk to which he was exposed from being intercepted and hemmed in, lost no time incommending his retreat upon Corunna. Napoleon was averse to all military action, and was unwilling to fatigue the troops under his command unnecessarily; he therefore recalled the marshal, with injunctions to pursue Sir John, and "drive the English into the sea." At the same time Marshal Ney was commanded to support the operation with the six French corps. Soult, who had been so long with the Austrians, with the anxiety so common with them to explain away any failure of the French arms, have, on this occasion severely censured Marshal Soult for inactivity and negligence, in halting at every defile to collect the sick and loiterers, by which he had delayed the whole army, and according to them, was prevented. On the other hand, the marshal always expressed his astonishment at the skillful retreat of his enemies. At length, on the 18th of January, 1809, the British army, having approached Corunna, the place intended for their disembarkation, made a stand, and a bloody engagement ensued. This action Sir John Moore was mortally wounded, but the French met with a decisive repulse. [Moors, Sir John.] The British troops effectuated their retreat by storming the town of Corunna, and it was not until the 30th that the Spanish governor capitulated.

Soon after, Marshal Soult entered the Portuguese territory with the 2nd and 5th corps; and having defeated the Portuguese troops under Romana, he advanced upon Porto, which was captured by storm on the 29th of March, 1809. Instead of marching at once upon Lisbon, the marshal lingered at Oporto, where he is said to have conceived the plan of making himself king of Portugal, and to have postponed the hereditary claims of his imperial master, while indulging this intrigue.

Meanwhile, Wellington had landed, collected his forces, and made his preparations; on the 8th of May he reached Coimbra with the English army, whilst Beresford at the head of the British cavalry, and the light infantry, and Amaranth to turn the French army. After passing the Douro with his usual boldness and promptitude, Wellington fell upon the marshal, drove him from his position, and captured his camp, his baggage, and almost all his guns. Soult then retreated upon Galicia, with a loss upon his route of 5000 men; whence, after leaving Ney, with his single corps, to defend that province, he continued his retreat to Zamora. The retreat was conducted in a manner creditable to his military talent, but he suffered his troops to commit atrocities on the helpless peasantry which have left an ineffaceable stain on his memory.

After the battle of Talavera, July 28, 1809, Soult was appointed to replace Marshal Jourdan as Major-general of the army in Spain, the chief command having fallen into the hands of King Joseph, a man without any capacity for war, but faithful and devoted to his brother's plans. On the 19th of November, 1808, he won the battle of Ocana, and, soon after resolved on an expedition against the city of Seville, one of the richest provinces in Spain. Accordingly, in January 1810, he collected a strong army, consisting of four corps, and taking his way through Andujar and Seville, appeared before Cadiz on the 6th of February; but was defeated at the battle of Albuera, on the 16th of May, 1811. He then returned to Madrid, leaving the marshal in command of the Army of the Sonth, consisting of the 1st, 4th, and 8th corps. The year 1810 was almost entirely occupied by the marshal in establishing his position in Andalusia; but the wide commanders over which his troops were dispersed, constantly
exposed them to loss in petty skirmishes with the enemy, who, supported by the strong fortress of Badajoz to fall back upon, had a great advantage over him. In the beginning of 1811, Napoleon, who felt the urgent necessity of supporting Massena in Portugal, ordered Soult to Badajoz, from which he captured the place on the 11th of March, 1811, the Prince of Essling, unable to penetrate the strong lines of Torres Vedras, had found it necessary to abandon Portugal.

The days which followed brought a brilliant line of victories that relieved the English army from one of their most formidable opponents, Lord Wellington determined to recapture Badajoz, for which purpose he despatched Beresford to invest it. The siege was opened on the 7th of May, 1811; Soult came to its relief, and with his forces in the battle of Albuera, in which he fought with consummate skill, though not with his utmost numbers he inflicted great loss upon Beresford's army—he was thoroughly defeated. The fall of Badajoz now appeared inevitable, when Napoleon, apprised of Soult's recent defeat, ordered Marshal Marmont, who had superseded Massena in the command of the army of Portugal, to push forward to his support. This movement rendered it necessary for Wellington to raise the siege on the 16th of June. However, in the following spring, encouraged by the capture of Ciudad Rodrigo, Wellington laid siege a second time to the fort of Badajoz, and—though not without terrible loss—the place was carried on the 6th of April, 1812. Soult was in consequence compelled to retreat from Seville, his rear-guard being saved by a shore-boat from the Tagus.

The subsequent defeat of Marmont at the battle of Salamanca (July 22, 1812), and the surrender of Madrid to the British general, compelled Joseph Bonaparte to withdraw both the Spanish and French forces, and Marshal Soult, at the creation of orders to join him. Accordingly, he despatched de Brevet, who marched out of Andalusia, and on the 10th of November took the command of the three combined French armies stationed on the Tagus. This junction of forces was too powerful to be attacked; Lord Wellington, therefore fell back upon Ciudad Rodrigo, with a heavy loss of troops on his route, and went into winter quarters. After his departure from the rich province of Andalusia, which he had occupied for nearly three years, the strongest charges were brought against Marshal Soult for the cruel extortion levied on the people by himself and his agents, and his shameless and unbridled robbery of pictures and articles of value. The reports of military men of every army engaged in the Peninsula war have fully corroborated the charges; while the enormous wealth which he ostentatiously displayed after the peace seemed to indicate that he did not feel the disgrace his atrocious conduct had drawn upon his name. For a few months during the year 1813, Soult was employed in the German campaigns, but being dissatisfied with the command of his troops, he requested the king to give him a post in the south-west. The king granted his request; but in order to mark his appreciation of the services of the marshal, Louis-Philippe re-established in his favour the ancient and disused dignity of Marshal-General of France, which had not been borne by any officer since the death of Marshal Turenne. From that time the marshal went to live in retirement, to which he confined himself more closely still after the revolution of February 1848. His health and strength had been undermined; the marshals grew worse during the year 1851, and breathed his last at the castle of Soult-Berg, on the 29th of November in that year. After his death his splendid gallery of Spanish pictures collected by him during his Spanish campaigns was sold by the Government; and it is ascertained that the best of these pictures are now in the Imperial Galleries of France. The Mémoires du Marshal General Soult, due de Dalmatie, published by ses fils, 1ère partie. Histoire des Guerres de Rvolution, appeared in three tomes. 8vo, with an Appen. Paris, 1833.

SOUTH AUSTRALIA. Under this head, in Supplement 1, an account of the geographical features of the colony was given. It has risen since to greater importance, and is better known. We therefore add the following particulars:

The climate of South Australia is one of the finest in the world, resembling that of the south of Italy. The atmosphere is generally clear and dry; and the grass is green and thriving, of the variety and brilliancy of its colours. There are no prevalent diseases. On entering the country some are attacked with dysentery, which with a little care may be avoided. Adelaide has been occasionally visited with influenza; and at particular seasons the sheep are beset with an epidemic of ophthalmia, which is rather a swelling of the eyelids, caused by a small insect. The seasons are divided into dry and wet. The dry season begins at the end of August and continues to the middle of November. At this time, generally, the days are warm or hot, and the nights cold, a difference of temperature corresponding to our June and July, the heat is very great, and the ground so arid that the least breeze raises clouds of dust. Occasionally in summer a hot wind from the north blows over the plains, and compels all to seek shelter. In winter a cloud of cold, heavy rain comes down from the south-west. The thermometer ranges as high as 115° Fahr. Its highest range in 1856 was 106°; its lowest,
During the summer period, from the end of March to August, it rains frequently and sometimes very heavily. During this period the earth is covered with the richest verdure, and the weather is so genial that the approach of summer is scarcely perceptible. In summer the grama grass grows luxuriantly and is so plentiful and tender that it is broken when trampled on; but the ground is as rapidly clothed with fresh pasture by the showers which fall at no great intervals. The long droughts, with which New South Wales is periodically visited, and the large extent of its fertile pasturage, preserve the species in a state of health and vigour, and they are found in considerable numbers on Kangaroo Island. For several years flocks have appeared in great numbers, and caused much damage to gardens and young crops in the district around Adelaide. Birds are numerous, and great numbers of quails and parrots are commonly seen. There are several kinds of snakes and lizards among the latter the iguanas, which is eaten; among shell-fish, oysters and periwinkles are plentiful. Turkeys and imported horses from Tasmania and New South Wales, and pouls from the island of Timor in the Indian Archipelago; cattle and sheep from the Cape, Tasmania, New South Wales, and Victoria; hogs from New Zealand. Fowls are common, both the common species and the larger one from the countries of the Malays. The kangaroo-dog is a valuable cross-bred of the dog-bulldog and greyhound, and is used for chasing the emus and kangaroos.

The woods of South Australia contain many large trees, of which the stringy bark, the hoop pine, and the red gum, with other genera of the Eucalyptus, are the most useful, their timber serving for building and fencing, for the construction of carts and ploughs, and the manufacture of agricultural implements; but timber for finer purposes is imported. There are several species of trees which yield large crops of grain which are successfully cultivated: maize grows well, and also potatoes. Melons, water-melons, pumpkins, and cucumbers attain an uncommon size, as do also cauliflower,

Onions are cultivated, to a great extent in Kangaroo Island. Every approved variety of grape is grown. No edible is indigenous, except some berries, which are eaten by the natives. Fruit-trees have been extensively introduced. At Adelaide a prize was awarded in 1851 for a collection of sixty varieties of apples grown about ten miles from the town. A few gardens have been established, and the oranges and limes and olives and mulberries, are cultivated to some extent. Every approved variety of grape is grown.

South Australia is rich in minerals. Iron-ore is found in many places, especially in the deserts. Copper-ore is very widely distributed in great abundance, and of the richest quality. Lead also; exists, in considerable quantity, and some gold has been found. Salt occurs in many places. Twelve copper-mines were in operation in 1826. These are --the Burra-Darra mine, 90 miles N. by E. from midland station, N. E. by E. Karkutie mines, 76 miles N. by W.; Worthing mine, 14 miles S.S.W.; Perseverance mine, 12 miles N.E. by E., where parties were engaged digging for gold on lodes; Theel mine, 25 miles N.E. by E., the Consolidated mines in Barossa and Lyndoch Valley, 33 miles E. by N.; the Kanyakoo, Bremar, Wheal Mary, Wheal Maria, and Wheal Friendship mines, all in a group about 25 miles S.S.E. from Adelaide. The ore of the Burra-Darra mine is peculiarly rich. It contains 70 per cent. of metal, in the form of a pure oxide requiring no flux to smelt it, the heat of a blacksmith's forge sufficient to reduce it. The lode is 17 feet wide, of great extent, and is carried up in steps, in lodes, and is divided from the stone, in veins, into masses of about 20,000 tons of copper ore, valued at 200 l. per ton. The lead mines are Glen Osmond and Wheal Watkins mines, about six miles south from Adelaide, and the Wheal Gawler and Yatagalonga mines, the first two yielding 76 per cent. of metallic.

The natives of South Australia, like those of New South Wales, belong to that race which is called Negro Australian. They have not yet attained an equal degree of civilization as the natives of the northern part of the eastern coast, but measures have been adopted for their improvement, and a prospect of success. There are schools at Adelaide and Port Lincoln for the education of the children. Connected with the latter is a training institution under the superintendence of Archdeacon Hare, in which the youths, after leaving school, are kept separate from the tribe, and instructed in the Christian religion and in some industrial pursuit. A number of youths are employed on stockholders' stations along the Murray. Though it appears certain that all the natives of the southern and eastern coast of Australia speak the same language, a marked difference exists in the dialects spoken in different parts. Various dialects are used within the territories of South Australia: one is spoken by the few isolated families who are preserved on the coast of the Gulf of Carpentaria; one is the language of the tribes inhabiting the vicinity of Adelaide, and the tribes along the banks of the Murray below the junction of the Darling, have been found to use four different dialects, of which three of which are unintelligible to natives from the neighbourhood of Lake Albert, and the one employed in the south-west of the colony is generally peaceable and inoffensive.

The settled parts of the colony have been distributed into the counties of Flinders, Sydney, Gawler, Light, Eyre, Adelaide, Sturt, Hindmarsh, Grey, Robe, Russell, all lying between the east coast of the Gulf of Carpentaria and the county of Flinders on the south-west coast of Spencer Gulf. A township has been laid out at Port Wakefield, at the head of the gulf of St. Vincent, where a considerable quantity of wood has been shipped for Sasseena. Roads and bridges have been liberally provided for as settlements have been formed.

The population of South Australia in 1854 was 97,387. The government of the colony is vested in a lieutenant-governor, an executive council, and a legislative council. The executive council consists of the governor, the colonial secretary, the advocate-general, and the surveyor-general. The legislative council, which was instituted in 1851, is the present of a small number, and the Imperial Parliament, passed in August, 1850, consists of 34 members, divided into the crown, and 16 are elected by 10c. householders and the possessors of freehold property of the value of 100l. sterling, in the 16 districts into which the colony is divided for the purposes of the local government. There are no municipalities in the colony, and the greater part of which is derived from the duties of 1s. per gallon on wines, and 10s. per gallon on spirits. There are no differential duties between British and foreign goods; but an 'ad valorem' duty of five per cent., or an equivalent rated duty, is charged on all imports except wines and spirits. The general colonial revenues in 1852 was 109,355l., the expenditure was 88,338l.; for 1855 the revenue had risen to 504,300l., and the expenditure to 510,237l., and of a total of 173,376l. being a small balance during the year on streets, roads, and harbours. The land fund revenue realised 223,746l. for 171,610 acres of land. The total exports in 1852, exclusive of bullion and coins, amounted to 795,871l.; the imports were 938,971l. In 1854 the imports amounted to 3,064,436l., but decreased considerably in 1855; while the exports had increased from 833,104l. in 1854 to 839,915l. in 1855, exclusive of gold, which in 1854 amounted to nearly half a million. The export and import trade show a considerable increase.

The government of education in the colony, an inspector of schools has been appointed. Schoolmasters obtain an annual grant of 20l. for the first 30 scholars, and 1l. for each additional scholar, the aid however in no case rising above 60s. The same amount is paid for each schoolmaster's residence. A school fund, amounting to 1,000l. was raised by subscription in aid of education is 1853, was 69, with about 3200 scholars. The amount paid to teachers during the year was about 3100l.

In 1850 there were about 180 places of worship in the colony. The ministers of religion were 17 of the Church of England, under the superintendence of the Bishop of Ade-
SOUTHERNWOOD.

"A"., Caroline Ann, (better known as Caroline Bouver), the second wife of Robert Southey, was the only child of Captain Charles Bowles, of Buckland, near Lymeington, Hampshire, where she was born December 6, 1787, and where she spent the whole of her days, with the exception of a few years, spent in the colonies. Her home was in the suburbs of the city, and she was known as "Caroline Bouver," or "Mrs. Southey," as she was the wife of Robert Southey, the poet. Her life was spent in quiet seclusion, and she died in 1861.

THE BURRA-BURRA AND OTHER COPPER MINES IN SOUTH AUSTRALIA.

The Burra-Burra and other copper mines in South Australia have been extensively worked, and are still in operation. The mines are located in the extensive copper belts of the Flinders Ranges, and are situated about 80 miles from Adelaide. The copper is of high grade, and the ore is easily worked. The mines are operated by a number of companies, and the output of copper is considerable. The copper is exported to many countries, and is used in various industries.

SOUTH AUSTRALIA.

The South Australian government has been in existence since 1851, and is the oldest state government in Australia. It is a representative government, and is governed by a council of ministers. The capital of the state is Adelaide, which is situated on the coast, and is a seaport city. The state is divided into a number of counties, and is bounded on the north by South Australia, on the east by Bass Strait, and on the west by the Great Sandy Desert. The state is also bounded by the Indian Ocean to the south.

SOUTHERMILTON.

A town in the county of Devonshire, England, and the seat of the See of Exeter. The town is situated on the river Tamar, and is a market town. The town is surrounded by a number of small villages, and is a center of agriculture and commerce. The town is governed by a council of aldermen, and is represented in Parliament by two members.

THE BURRA-BURRA AND OTHER COPPER MINES IN SOUTH AUSTRALIA.

The Burra-Burra and other copper mines in South Australia have been extensively worked, and are still in operation. The mines are located in the extensive copper belts of the Flinders Ranges, and are situated about 80 miles from Adelaide. The copper is of high grade, and the ore is easily worked. The mines are operated by a number of companies, and the output of copper is considerable. The copper is exported to many countries, and is used in various industries.
her husband's letters, which have since been edited by Mr. Warter. The poetry of Caroline Bowles is of a kind that will always give pleasure to persons of a reflective turn of mind, but it is not likely to deserve tender, graceful, and, though somewhat melancholy, pervaded by a fine moral tone; but it is diffuse, and wasting in strength of thought and passion.

SOUDET, EMILIE, one of the most able writers of the present day, was born at Morlaix, in Brittany, on the 15th of April 1806. His father was an engineer officer employed in repairing the roads and bridges of his district. Educated at the college of Pontivy until he had reached the age of 15, he began to be decided on a taste for literature. But his father's death in 1823 induced him to select the bar as his profession. He therefore studied the law, and in 1827 was formally received as an advocate at Rennes. He soon however gave weary of waiting for practice, and proceeded to Paris, with a strong determination of setting up as an author. His first efforts in this way were not encouraging. Having written a drama, the 'Siege de Maloslong,' it remained unnoticed at the theatres until M. Alexandre Donat, a Breton like himself, and already known as a successful dramatist, supported him with his interest. After this his tragedy was read, accepted at the Théâtre Français, and put into the prompter's book. But then came the 'censure' with its pruning knife, and such was the moral that soon after he had written it he had before appraised it. Thus disappointed of his hopes, he returned to his family, and being left without resources, accepted a situation as shopman with M. Mellinet, a bookseller at Nantes. In this situation he was living when the Jersey painter, Charles X., gave so much stimulus to the young generation.

He began in 1830 to write for the provincial press, and in 1832 was appointed managing editor to a liberal journal published at Nantes. While living with M. Mellinet, Émile Souvestre was frequently noticed by the customers who frequented the library, for his unobtrusive good sense, and one of these, the deputy Léminais, a gentleman devoted to the reform of national education, conceived a friendship for him. This deputy was a Breton, and was naturally flavoured with the national interest in the same object, and having founded a school at Nantes for the illustration of his new plan, he entrusted the management of it to young Souvestre, and another youthful reformer, M. Papot, under whom its success was from the first decided. In 1835 M. Souvestre was made régent de rhétorique at the college of Malhonne, in Alaise; he did not however continue many months in this situation.

For several years he had been quietly collecting materials to produce a work on his own province, to which he was extremely attached. This he did in 1836, under the title of 'Les Derniers Bretons,' a book which at once established his name. It is one of the best descriptions of Britany, full of vivid illustration and supported by the customs, manners, and literature of the 'Wales of France.' His 'Échelle des Femmes' appeared at the same time, and was likewise successful. Encouraged by this change of fortune, Émile Souvestre returned to Paris to fix himself there. He was then thirty, and his future lot was decided. For the next twelve years, 1836-48, he took a prominent part in the rédaction of the 'Réve de Paris,' and the 'Réve de Deux Mondes;' he also contributed many notices and articles to 'Le Temps,' 'La République,' 'Le National,' the 'Scole,' and the 'Journal du Commerce.' His style is very pleasant, his matter thoughtful and instructive. His articles, tales, and books have none of the levity, or persiflage, so lamentably common in too many of his contrymen in the present day; they may be taken up with full reliance on their taste and tendency. Among his numerous writings may be cited: his 'Voyage dans le Finistére,' 'La Maison Rouge,' 'Le Mat de Coqagne,' 'Pierre et Jean,' and 'Les Confessions d'un Ouvrier.' The last is a story of a thousand, full of maxims of the soundest character, especially as relates to the industrial classes. He has also produced several successful dramatic pieces, amongst others: 'Le Fil de tout le Monde,' 'Le Riche et le Pauvre,' 'Henri Lamennais,' 'Aine de Cadet,' 'Un Misantheme,' 'Un Messager de l'Amour,' 'Un Enfant de Paris.' He is also the author of a good history of the Revolution of 1848.

In 1848, Émile Souvestre, who never lost sight of the principle of educational reform, was appointed by M. Carnot, then minister of public instruction, a lecturer in one of the schools established for the civil service. He likewise gave gratuitous lectures in the evenings to large audiences, consisting of working men and their families. These lectures were well calculated to produce a beneficial effect, and were always crowded.

In 1853 he spent the summer months in lecturing in the principal towns in Switzerland. These lectures were also very successful. He seemed to have found a new vocation, and had begun to diffuse new and more rational notions on a class, who do not always think for themselves, when his health gave way, and death put an end to his useful labours, on the 6th of July 1854. Having married a second time, he left behind him a widow and three daughters.

SOWERBY, GEORGE BRETTINGHAM, second son of James Sowerby, one of a numerous family distinguished as naturalists, or natural history artists, was born at Lambeth on the 12th of August 1786, and died on the 36th of July 1854. He studied natural history with more success than his elder brother, perhaps on account of his not being so good an artist.

In early life he was attached to the study of Entomology, and assisted his father in those departments of his labours where a knowledge of insects was required. On marrying however he gave up his Entomology, and commenced business as a dealer in natural history objects, and visited the Continent of Europe for the purpose of obtaining specimens. He bought the celebrated Tankerville collection of shells, for which he gave six thousand pounds. He also bought several other large collections. His knowledge of the forms of shells was very extensive, and he projected and published a great work entitled 'The Genera of Recent and Fossil Shells.' This was published from 1820 to 1834. His father and brother executed the plates, and he wrote the descriptions. His papers on various species of Mollusca are very numerous, and were published in the 'Zoological Journal,' the 'Proceedings of the Zoological Society,' the 'Magazine of Natural History,' and the 'Reports of the British Association.' A list of these papers, upwards of forty in number, is given in Agassiz's and Strickland's Bibliography of Zoology, published by the Ray Society. Besides these papers and the work on the genera of shells he published several volumes for which he was much esteemed. These should be mentioned the Catalogue of the collection of the late Earl of Tankerville, 'Species Conchyliorum, or concise original Descriptions and Observations of all the Species of recent Shells with their Varieties,' London, 1830. 'Cockeyological Illustrations, or coloured figures of all the hitherto unfigured recent Shells, with their Varieties,' London, 1832-35. 'Thesaurus Conchyliorum, or Figures and Descriptions of Shells,' London, 1842. He was a Fellow of the Linnean Society.

SOWERBY, CHARLES EDWARD, third son of James Sowerby, was born on Feb. 1st, 1795, and died in June 1842. He assisted first his father and afterwards his brother James de Carle in their natural history publications till 1831, after which he spent many years in the English Colonies. In 1831 he commenced the publication of a second edition on small paper, with large additions. This work has been reprinted by his son, John Edward Sowerby.

SPAN. Since our previous account very material alterations have taken place, which we shall briefly indicate. The first is the sub-division of the old provinces for administrative purposes, which we subjoin, with the population in 1849, the latest return available; but by a return not yet published, the total population it seems amounts to about 17,000,000.

</table>

Commerce and Manufactures—Spain, from the extent of its coast-line, its large ports of Cadiz, Cartagena, and Ferrol, the number of its smaller barbers, its geographical position, and its abundance of natural productions, possesses very great commercial advantages, but those advantages have been diminished, and in a great measure destroyed, by the restrictive laws of the government. Smuggling to an enormous extent is carried on almost everywhere along the coast, especially at and near Gibraltar, and also from France, across the Pyrenees, and from Portugal across the frontier. The articles smuggled through Gibraltar consist of cloth, sugars, muslins, thread, stockings, and the like, and tobacco to a large extent. The total import into Spain during 1849 amounted to 857,171,795 reals (about 6,160,000 l.). Of course these are the registered imports. The amount of goods smuggled into the country cannot be estimated. The exports during the same year amounted to 476,129,823 reals (about 6,000,000 l.). The imports consist of colonial produce, dried fish and salted provisions, cotton and woollen goods, cutlery, glass, butter, and cheese. The exports consist of wool, wines, brandy, oil, fruits, chestnuts and nuts, cork, quicksilver, hides, lead, and salt. The exports of silk and manufactured goods. Of late years a large amount of wheat and flour has been exported from the northern provinces, chiefly to Cuba and Brazil. The manufacturing industry, formerly considerable, has greatly declined; and the grape-vine disease (oidium) has very materially lessened their manufacture and exportation of wine. The government has still manufactures of tobacco, saltpetre, gunpowder, cannon, fire-arms, and porcelian, but they are all in a decayed state except the manufacture of cigars at Seville. Other manufactures are silks, coarse cot开关, and woollens, and leather. Cutlery and iron-ware are made to some extent in the Basque Provinces and Asturias.

Roads, Canals, and Railways.—The public roads in Spain, except those belonging to the capital and going to market, are not bad. Madrid through Leon to Oviedo and the coast, are amongst the worst in Europe. The only canal of importance is the Imperial Canal, commenced by Charles V., extending along the southern bank of the Ebro. There are three or four smaller canals in the province of Castile and its territory, none of which was completed in January 1858, are—from Barcelona to Arenis del Mar, 23 miles; from Barcelona to Granollers, 19 miles; from Barcelona to Martorell, about 20 miles; from Barcelona to Tarrasa, 25 miles; from Valencia to Alcudia, 39 miles; from Valencia to Alcoy, 3 miles; from Madrid to Albacete, 173 miles; Reina to Alar del Rey, 32 miles.

Revenue.—The budget proposed for 1857 amounted to 20,030,000 l.; the ordinary receipts were estimated at 17,681,000 l., leaving a deficiency to be supplied of 2,350,000 l. The amount of the public debt in November 1856 was 141,200,000 l., on which the interest payable was 2,277,000 l., in addition to a loan for 8,330,000 l. recently contracted for.

The army and navy are given under MILITARY AND NAVAL FORCES, &c.

Religion and Education.—The established religion is the Roman Catholic, and no other is allowed in the Spanish dominions. The crown presents the archbishops and bishops, who are confirmed by the Pope. The wealth of the church was at one time immense. After the suppression of the nunneries and monastic orders were suppressed, and the convents and the lands belonging to them were sold; but the convents of nuns were suffered to remain till the death of the then occupants. A laicization of the estates in 1835 for the benefit of the church-property, and its conversion to secular uses; which law was revoked, at least so far as the property nunnels, in 1857; and an indemnity to the clergy of upwards of 2,500,000 l. has been granted to the Cortes, but has not yet (May, 1858) been adopted.

Education is very little diffused. The lower classes receive little or no instruction, except in the principal cities, where infant-schools have of late years been established. The children of the upper classes are mostly educated in private schools and universities. The universities and monasteries, and of great reputation, are now reduced to about 14, and those are attended by only a comparatively small number of students in theology, law, and medicine. There are, however, several medical and literary societies in Madrid, Sevilla, and other large cities.

History.—After the queen-mother, Christina, had been appointed queen-regent (Reina Gobernadora), Don Carlos, the brother of Fernando VII., laid claim to the throne on the ground that the Salic law female line was ineligible. A civil war ensued, which lasted till September, 1840, when the partisans of Don Carlos were finally defeated, and the sovereignty of Isabella established. Early in 1854, in consequence of the arbitrary and unconstitutional measures of the Spanish government, insurrections occurred in Barcelona and other places. On the 22nd
of February the whole kingdom was declared in a state of siege. On the 15th of July the city and garrison of Paris were carried by storm. The streets were barricaded, and the people fought against the soldiers till July 17, when the ministry fled, the soldiers gave up the contest, and a National Guard was formed. The above events were not the end, but the beginning of a revolution. The constitution of the government was re-established; and the queen-mother was banished from the kingdom, August 28, 1684.

In June, 1686, a revolution took place, and General O'Donnell was killed. The force of arms. He was succeeded by Marshal Narvaez in October. Narvaez was dismissed in the following year, and was succeeded by M. Isturitz, as prime minister, but the government is yet in a very unsettled state.

Spanish.

Species of plants. All the individual forms of plants, as well as animals, that occur on the globe, may be collected into groups resembling each other, and these groups are called species. A species has been defined to be "a combination of individuals alike in all their parts;" "a species..." a collection of individuals which will breed together and produce fertile offspring." De Candolle says, a species is a collection of all the individuals which resemble each other more than they resemble anything else, which can by nurture and their future alsoreproduce themselves, by generation, in such a manner that we may from analogy suppose them all sprung from one single individual." However clear such a definition may be, it would assist a botanist only in a very limited degree in determining whether a new plant should be looked upon as a new species. If there were perfect structural identity between two individuals of the same species, or if we could ascertain, on the physiological ground, that the individuals after fertilization reproduced similar individuals, there would be no more to be done than to name the new one. But perfect structural identity does not exist, and the physiological test cannot be always applied, and hence the difficulty of determining what is really a species. From this same source go so far as to deny the existence of species altogether, and assert that the supposed distinctions between plants are altogether arbitrary and imaginary. This notion is however altogether upset by the well-known fact of plants maintaining for centuries the same structural character.

De Candolle says, "one acquires the idea that the variations multiplication of species, that some fixed rules cannot be laid down for their formation, it does not appear at present that anything more than general rules can be given, and that much must depend on the judgment and experience of the botanist." As a general rule species are not distinguished by differences in the internal organisation, such differences being left for the higher divisions into genera, orders, and classes; but by those superficial and external differences which are independent of internal structure. Of these may be named duration, dimension, surface, form, division, numerical proportion, and colour. The value of each of these points varies according to circumstances, and in proportion to the knowledge of the observer will be the skill with which he selects them for distinguishing species. The duration of a plant is a point of great importance, as in no instance do we find, unless from change of climate, plants of the same species differing in being annual, biennial, &c. Dimension, however, is a subject of great importance in cases of extreme consideration in extreme cases. Differences of surfaces, depending on structural peculiarities, are of importance; smoothness, roughness from tubercles, and the existence of the presence or absence of symmetrical hairs on the surface of leaves is a point that may mostly be disregarded; they are of more importance on other parts. The form of parts is only of importance when it is the consequence of anatomical difference. The division of organs is not of much importance where it depends on the degree of the laceration of the parenchyma. The union or non-union of contiguous organs, as the parts of the calyx, corolla, &c., is of the greatest value, being mostly uniform in all the individuals of the same species. The

numeral proportion of the parts of a plant is of value in proportion to the small number of parts or organs; the greater the number, the more subject it is to variation. Differences in colour, odor, or taste, are little to be relied on.

These departures from identity of structure, which are considered insufficient to constitute a species, are called varieties, and the points of structure that should constitute a species are called a VARIABLE. Species is a term which is no longer used in botany, and it is no longer the term for another to author and reductie the species of another to mere varieties. Thus, Borrer has made 71 species of Stink, but Koch has reduced them to 29, and the species of Stink are of vast number, and are the result of the influence of climate, soil, elevation, &c., on species, would save much trouble and vexation on this point. De Candolle has elegantly summed up the influence of these agents on plants:— "Let us suppose," he says, "what really happens, that the seeds of plants are scattered at hbird on the surface of the earth; and, to speak more correctly, by causes that have no necessary connection with the existence of those plants; such seeds will find themselves in an infinite variety of situations; some which have fallen in soil that is too tenacious or too loose, too very or too wet, too hot or too cold, do not grow, and are soon destroyed. But between these extremes some will succeed, although it may be under very different circumstances. Thus, for instance, if the place were not light, the plant will be half blanched, which will be indicated by its paleness and feebleness, or by being spotted, or by the diminution or even loss of its hairs; if the light is too bright, the plant will be stronger, smaller, more deeply coloured, harder, and more velvety than usual. Temp-erature is also a cause of variation, and in a cold climate the same plants are smaller and weaker than ordinary, the color of the flowers and fruit is paler, the wood worse ripened, their leaves more deciduous, their fruit often abortive, and the sap destined to nourish it throwing itself into the formation and development of the leaves; and in water it will lose all their hairs, a greater number to the capillary segments so as to look like hairy roots, their stems and flower-stalks lengthen to reach the surface of the water, and these different effects are further variable as the water is still or agitated, clear or turbid, pure or mixed with heterogeneous substances; the varieties of Ranunculus aquatilis offer a remarkable example of this. If, on the other hand, a plant accustomed to water is found to live in a drier soil, it becomes covered with hairs, remains smaller than usual, and in other cases it will become large, fleshy, and fully formed; if it contains a great quantity of carbon, the colours of the flower are often altered, as those of the Hydranga into blue, and of the Pink into violet; if it is charged with salt, or if the plant is within the salt of the earth, even brought through the atmosphere, we usually find the leaves more fleshy and more glaucous, as in Loctes corniculatis. All these different circumstances, combined with each other in nature, are fertile causers of varieties, which are still further multiplied by cultivation."

Spontini, Gaspard. A famous Italian dramatic composer, born at Jesi, in the Roman States, in the year 1775. After studying the principles of music under Padre Martini at Bologna, he entered, at the age of thirteen, the Conservatorium at Naples. His name became known through his school of great renown. At seventeen he composed his first, "Pentigilli delle Donne," which spread his name over Italy, and led to the favourable reception of a long series of dramatic productions. He visited Paris in 1804, and from that time became known and popular in all the principal cities of Europe; he enriched his principal works, "La Vestale," "Olympia," and "Fernand Cortez," having been composed for and produced at the Académie Royale de Musique. Of these works "La Vestale" acquired the greatest celebrity. Having been adapted both to the Italian and the German stage, it was
performed in every great musical theatre in Europe, and for a time had almost as much popularity as the works of Rossini himself. Spontini passed many years of the latter period of his life at Berlin, as director of the Prussian opera, and held this office at the time of his death, January 21, 1851.

STAIRS. [etc.]

STALEYBRIDGE, Lancashire, a market-town in the parish of Ashton-under-Lyne, is situated chiefly on the right bank of the river Tame, in 53° 30' N. lat., 2° 4' W. long., distant 8 miles E. by N. from Manchester, 16 miles N.W. by N. from London, and 193 miles by the London and North-Western railway via Trent Valley. The population of the town in 1851 was 20,786. The living is a perpetual curacy in the archdeaconry and diocese of Manchester. Stalybridge owes its importance chiefly to the cotton manufacture. Woollen-cloth is manufactured to some extent; there are also brass and iron foundries, machine-making factories, brickfields, collieries, stone-quarries, and cornmills. The parochial chapel is an octagonal structure occupying an elevated site, and there are two distinct churches, chapels for Wesleyan, Primitive, New Connexion and Association Methodists, and for Independents, Baptists, and Roman Catholics; National, British, and Roman Catholic Schools, and also a dispensary, and savings bank. Saturday is the market-day; fairs are held on Easter Monday and November 5th.

STAMP ACTS. See 17 & 18 Vict., c. 83; 18 & 19 Vict., c. 30; 18 & 19 Vict., c. 82; 18 & 19 Vict. c. 27; 18 & 19 Vict. c. 30 and 18 & 30 Vict.

STAMP DUTIES. That the relaxing of a heavy tax, while it confers great advantages on the public, does not always involve a loss of revenue, has been strikingly shown in the example of the postage rates, as well as in many others, of which the Stamp Duties form one. In 1850 and 1854 great alterations and reductions were made by the 13 & 14 Vict., cap. 97, the 16 & 17 Vict., caps. 59 & 60, and the 17 & 18 Vict., cap. 53. That the acts were altogether a great boon to professional men, and to the public at large, is plain from the returns which there are not two opinions. The effect upon the revenue will be seen from the following figures:

In the year ending Jan. 5, 1850, the sum produced by the Stamp Duties was £5,867,548
In the year ending March 31, 1858... £7,572,509

It must, however, be taken into account that the Succession Duty on real estates was passed in 1853. But in 1858 the stamp duties yielded £6,763,259; and the penny receipt duty has come into operation since.

In pointing out the difference between the former and the new duties, the ad valorem duties first claim attention.

Conversion of the Shilling into the Dollar.—These duties show a considerable reduction in all purchases for sums not exceeding 500,000/. The highest ad valorem duty under the late law was 100/, there being no increase on sums exceeding 100,000/. The duty is now one uniform rate of 10/ per cent., without limit; which, speaking in general terms, may be said to be about half the amount of the former duty on sums from 500/ to 100,000/. That duty was not a uniform rate, as at present, but a fixed amount on all sums between those specified in the same stamping, some at more or less than 1/ per cent., as the purchase money approximated to the higher or lower amount in each step; on the mean sum it was precisely that rate. But on sums under 500/ the rate was, for the most part, much higher, being as much as 3/ per cent. on the mean sum under 20/; 3/ per cent. on that under 50/, and 1/ 10s. under 150. On purchases of small properties, therefore, the advantage is very great; and, referring to these, the justice and propriety of the language of duties will be more apparent. In giving a comparative statement of the two duties a difficulty arises from the difference in the language of the two acts imposing them, in expressing the turning point; in the new act the words "exceeding" and "not exceeding" being substituted for "amounting to" and "not amounting to".

The omission to charge the ad valorem duty on conveyances where the consideration was stock, whether in the funds, or of any company, is supplied.

The following table will exhibit a glance at the difference between the old and the new duties in all cases of sales for sums not exceeding 1000/.

Bonds and Mortgages.—These duties are also charged at a uniform rate throughout, viz., 2/ per cent. for every 100/, and any portion of 100/, except that on sums not exceeding 300/ the duty is imposed by fifties, so as to charge only 1/ 3d. on the fraction over 50/, thus favouring minor transactions, instead of the more important ones as under the old system. The rates are too low to adjust and weigh up the principle; as will be perceived when it is stated that the duty on the mean sums in the scale, from not exceeding 60/ to not exceeding 20,000/ gradually diminished from 4/ per cent. to 2/ 3d. per cent. on the highest duty being 4/ on 40,000/ or over, 2/ 3d. per cent., and that this rate proportionately diminished with the increase in the amount of money secured.

The following is a comparison of old and new duties on bonds and mortgages for sums not exceeding 20,000/—

</table>

At this point the old duties stopped, there being no increase beyond 25/, whatever might have been the amount of money secured; but the new duties continue on, ad infinitum, at the rate of 1/ 6s. for every additional 1000/, and in proportion for less than 1000/.

A mortgage, or (as in Scotland) a bond without penalty, for securing money to become due, without limit, is available as a security for such an amount, only, as the duty thereof extends to cover. In other cases the duties of the old duty is charged on the amount of the penalty.

A mortgage for securing money by way of rent-charge or annuity is chargeable with ad valorem duty on the money advanced. The case of an advance of money under the private Drainage Act (12 & 13 Vict. c. 101) is referred to in the work of a writer on the stamp laws (supplement to Tilley's Treatise on the Stamp Laws, p. 26) as an instance in which this will apply. The rates on annuity bonds are somewhat varied. Where the annuity does not exceed 100/, relief, to some extent, is given; above that amount there is an increase,
which is greater as advance is made upwards. The new duty is 2l. for every 100l., and any fraction of 100l. per annum; the former duty was not a per centage, but, as in other cases, according to a scale, but not extending beyond 2000l. a year. The present duty is not limited.

A new duty is now only to be charged on bonds given for any other purpose than as a security for money, where the penalty is of comparatively small amount. Under the old law the duty in every such case was 1l. 15s., or some other fixed sum; it is now the same duty as would be payable on a mortgage, and where the mortgage is relatively of greater value, as the penalty, where such latter duty is less than the fixed sum. Bonds given as a collateral or additional security for money are likewise charged with ad valorem duty where it would have been charged in an ordinary mortgage. The former duty was charged as an annuity, or as the penalty, where such latter duty is less than the fixed sum. Bonds given as a collateral or additional security for money are likewise charged with ad valorem duty where it would have been charged in an ordinary mortgage.

Leases.—Under this head the equity of the new system, by comparison with the old, will perhaps be more striking than under any other. The present rate of duty on the rent is 10s. per cent.; imposed thus, viz., where the yearly rent exceeds 100l., then for every 50l., and any fraction of 50l.—6d., but upon rents of lower amount than 50l., the proportionate duty is charged in smaller steps, involving a less amount of duty for any fraction; thus, again, having favourable regard to matters of comparatively small value, and reverting the former system, the rates are still based on the mean sums in the scale, were as follows, viz. 10s. per cent. on rents under 20l.; 6d. per cent. on rents under 100l.; 1l. 6s. 8d. on rents under 100l.; and gradually decreasing to 1l. 15s. on rents of 1000l. or upwards being 10l. only. Relief for the most part to the agricultural interest no doubt prompted the adoption of so liberal a measure, but it will be found, perhaps, more extensively advantageous to the owners and occupiers of land.

A lease of minerals reserving a portion of the produce, by reference to an annual maximum or minimum amount, is to be charged with duty on such amount; and where the fine or rent consists of coal or gas, and the duty is charged on the value, to be ascertained where there is no special contract by the returns published under the Tithe Commutation Act, or, in Scotland, the fairs prices of the county.

Assignments and surrenders of leases (not upon sale or mortgage) are to pay the same ad valorem duty, if not exceeding 1l. 15s., as the lease itself would be liable to. The duties on leases in Ireland are to be the same as in England.

Settlement of Money.—All the advantage afforded by the new Act in respect of the ad valorem settlement duties is on sums not exceeding 600l. The new duty is 5s. for every 100l. unlimited, and any fraction of 100l. The lowest duty under the former law was 1l. 15s., which extended to cover any provision for payment, the interest amounting to 20,000l. or upwards; being 7s. per cent. on the mean sum under 1000l., and averaging less than 2s. 6d. on the mean sums above 1000l., and under 20,000l. Thus the order of taxation is again rightly reversed.

These are the ad valorem duties affected by the new Act; and they may be said to be the only ones connected with the transfer of property by way of sale or security. Reference will now be made to other alterations which affect almost uniform relief.

Transfer of Mortgage.—This is an important branch of conveyancing; but it appears from the work of the writer already referred to, that it is one that has been more perplexed than any other by the Stamp Duties; and the result of much discussion of a very minute kind, or rather of examining previously existing, was to inflict an amount of charge not considered to have been intended by the legislature. The shifting of a mortgage security from one to another is always a cause for vexation to the debenture; but to the poor man it is a matter of serious moment. Independently of professional charges for investigating the title, and for preparing the conveyance, the stamp duty was, of itself, an intolerable burden. The lowest ad valorem mortgage duty, oppressive as it was, amounted to 1l. 15s.; and as in every instance a new covenant was, as a matter of course, contained in it, a further duty of 1l. 15s. became, under a recent authority, chargeable; making 3l. 10s. (besides a third stamp of 1l. 15s. for the duty on the lease of the property) charged on every transfer of mortgage, whether the money secured was under 100l. or above 20,000l. This is now remedied. The maximum duty on a transfer of mortgage is 1l. 15s.; and where, if the transaction was a mortgage, instead of a transfer, the ad valorem duty would be less than 1l. 15s., then such ad valorem duty only is to be charged. Thus, for example, on a transfer of a mortgage for 100l., the stamp duty, instead of 3l. 10s. as the lowest amount, as heretofore, is now only 1l. 15s.; and on all transfers where the money secured does not exceed 1400l. further proportionate relief is given. Where, on a transfer, further money was advanced, the ad valorem duty on such further advancement is chargeable in like proportion, under the new law. Thus, if for 1l. 15s. in all cases, are now charged with that amount as a maximum, the ad valorem duty being payable where less than 1l. 15s.

Further Advance.—Besides the duty on the further money lent, 1l. 15s. was necessary if the deed contained any additional security, by covenant or otherwise, for the original sum. Now, merely the ad valorem duty on the further advance is requisite.

Bargain and Sale (or Lease) for a Year.—Whilst the cumbersome mode of conveyance of freehold property by actual lease and registered warrant has been superseded, there is no inconsistency in imposing a stamp duty upon each of them; but when, by modern enactments, that system was superseded, and one of the instruments ceased to have, in its practical effect, any existence, it may be felt that it is inconsistent, as it was felt to be exceedingly inconvenient in practice, to encumber the other deed with the duties on both; but so it was; the release, or grant which had a new conveyancing principle given to it, was charged with the duty before the Act, 1l. 15s., and 1l. 6s. 8d. on the year, as well as that which was properly its own. These duties are now swept away entirely. Under the title Co-ownership certain additional duties were imposed on a feuference or bargain and sale executed as instruments of the duty on a lease for a year; these are, of course, removed.

Progressive Duties.—A vast improvement will be effected in conveyancing when any system can be established which shall materially curtail instruments in their verbosity. Something has been attempted by the legislature in this way, but without, at present, producing in general practice any alteration. The great length to which a deed may extend is by no means an indication of the value of the subject-matter; and it is sufficiently oppressive that, to effect a transaction of perhaps 200l. in which a petit clears of charge and makes his title, an instrument of considerable length must be created, swelling the professional charges to an inordinate amount; but the burden is increased by stamp duties imposed, without regard to the amount of any one of them, and thus are imposed on papers referred to in certain instruments as part thereof but not annexed. A provision is contained in the Act (section 11) that progressive duties shall not be, or be deemed to have been, chargeable on any instrument in respect of any other instrument, liable to stamp duty, and only stamped, incorporated with or referred to in it; so that an old document, duty stamp-d per se, may be made to form a part of a new one without being taken into account in calculating the progressive duty on the latter.

Duplicates and Counterparts.—In the case of settlements of money and a few other instances where ad valorem duties are payable, duplicates were expressly charged with the same duties as the original instruments; and counterparts became also liable, in some cases, to the like duties; but, in general, they may be stated to have been subject to a duty of 1l. 15s. except as to leases, the counterparts or duplicates of which were exempt by virtue of the date on which they were charged with 3l. 10s. These duties are now reduced to 5s. as a maximum, with progressive duties of 2s. 6d. the same duty, including the progressive duty, as the original, being imposed where such duty exclusive of progressive duty is less than 5s.

Memorial.—The duty on a memorial for registering a deed is reduced from 10s. to 2s. 6d.

Copyhold.—In all cases of sale and mortgage of copyhold
property the instruments charged with ad valorem duty are, of course, liable only to the new duties; but there is one instance in which the instrument was not subject to ad valorem duty. In the case of an admissibility the instrument was charged with 11½, or, where the yearly value did not exceed 14, with 5s. By the new Act these duties are reduced from 6s. ad. to the admissibility, and the case, 11s. ad. on a mortgage. In all other cases the duty on an admissibility remains as before.

Covenant.—A particular duty is now for the first time charged on a deed of covenant. It was, it seems, apprehended that the ad valorem being a common-sense, a practice might be resorted to of executing a covenant, as a security, which would be liable only as a common deed to 11½s., in lieu of giving a bond; it was therefore thought proper to impose the same ad valorem duty on a deed of covenant as on the latter. But relief is given in the case of a separate deed of covenant, executed on the sale or mortgage of any lands, for title, &c. by imposing 10s.; or less, where the duty on the conveyance is.

Agreement.—The duty of 2s. 6d. on an ordinary agreement remains as before, except that this amount is sufficient for any number of words less than 30 folios, instead of merely a quantity not exceeding 15 folios. But in lieu of the duty on the first 15 folios in any agreement exceeding quantity, and of 1½s. for every additional quantity of 15 folios, the duty now is 2s. 6d. for every such further quantity.

The advantage of this may be illustrated by the following example: suppose a contract for the performance of any work, and specified in words amounting to 100 folios, the figures amounting altogether to 100 folios, the duty under the old law would have been 11½s., and five times 1½s. for five entire quantities of 15 folios after the first, making altogether 70s. 6d. By the new law the duty imposed is six times 2s. 6d., making only 15s.

Charter, Precept, Resignation, and Seisin.—The duties on certain instruments in Scotland under these heads, are reduced from 9s. to 5s.

Warrant of Attorney.—The duties on securities of this description are as before, the same as on bonds, with a reduction of the duty on a warrant of attorney given as a collateral security, from 11½s. to 5s., where the duty on the principal instrument exceeds that amount; and also, where it is given for money exceeding 500l. for which the person giving it is under arrest. A warrant of attorney given for any other purpose than as a security for the payment of money or the transfer of stock is charged with 11½s., which is an increase, the former duty in such case being 11½s.

The foregoing are all the cases in which the duties have been altered by the new Act; but there are some material provisions which it will be proper to glance at.

The provisions of former Acts relating to Stamp Duties are kept in force, including exemptions. Certain agreements for setting lands in Ireland which were charged with ad valorem duties as leases, but which, if in England would have been subject only to the duty of 2s. 6d. as agreements, are to be deemed to have been liable to the latter duty.

Any person receiving money for stamp duty (including legacy duty) and not applying it, is to be accountable to the Crown by summary process.

Transfers of mortgages, further charges, and further securities executed before the 11th October, 1850, are not to be deemed to be liable to the additional duties already pointed out and attaching by reason of the decisions alluded to, but, in this respect, are to be put upon the same footing as those executed subsequently.

The terms on which instruments may be stamped after execution are materially varied. The penalty, in ordinary cases payable on stamping an instrument executed before the passing of the Act is 6d. upon payment of which and the duty, the stamp may be affixed. By the new Act the penalty is 10s.; and where the duty required exceeds 10s., then, further interest at 6l. per cent. per annum on the duty, calculated from the time of not first execution of the instrument; but no amount of interest beyond that the duty is to be paid by way of penalty. In lieu of a receipt for the duty and penalty as formerly, a stamp denoting the payment of the duty is to be impressed. One advantage to the party is however given. Under the old law, if an instrument was stamped, but with an insufficient amount, the whole duty was to be paid without regard to what had been already paid besides the penalty; but now, the deficient duty only is required.

Where instruments are executed abroad, the commissioners are empowered to stamp them without penalty at any time within two months after they are received in this kingdom. Until this Act there existed no power to determine what stamp duty was payable in any case, so as to assure parties that the stamp on an instrument was sufficient. The Commissioners are now invested with a power to adjudicate in all such cases, and to certify by means of a particular stamp, that the instrument is duly stamped, and so to preclude all question upon the point. The fee for obtaining this adjudication is 10s. An appeal is given to the Court of Exchequer.

The duties in Great Britain and Ireland are now assimilated, but it appears that a deed liable to Irish duty could not be stamped in London; and vice versa: this is now permitted.

By the Act of the 12 & 13 Vict. c. 80, the discount of 7½, 10s. per cent. allowed on the purchase of receipt stamps, was taken away; by the act now under consideration it is restored.

Licences to insure against fire both in Great Britain and Ireland are necessary before any such insurance can be made; but they were all formerly required to be obtained annually, but by the Act c. 79, such licences in Great Britain were to be permanent; the same provision is by the recent Act made as to Ireland.

One or two examples have been already given of the benefit to be derived from the new scale of duties in particular transactions, which are of common value; it will be well to furnish as instance or two more.

Take the case of a sale of freehold property for 150l., the conveyance consisting of 40 folios, that is one entire quantity of 2s. 6d. By the Act of 1850, after the first, and requiring, therefore, one progressive duty. Under the old law the duties would be as follows:

<table>
<thead>
<tr>
<th>Z. S. D.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ad valorem duty</td>
</tr>
<tr>
<td>Ditto in lieu of a lease for a year</td>
</tr>
<tr>
<td>Progressive duty</td>
</tr>
<tr>
<td>Total</td>
</tr>
</tbody>
</table>

Under the new Act the duties are:

<table>
<thead>
<tr>
<th>Z. S. D.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ad valorem duty</td>
</tr>
<tr>
<td>Progressive duty</td>
</tr>
<tr>
<td>Lease for a year</td>
</tr>
<tr>
<td>Total</td>
</tr>
</tbody>
</table>

They are now—

<table>
<thead>
<tr>
<th>Z. S. D.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ad valorem duty</td>
</tr>
<tr>
<td>Progressive duty</td>
</tr>
<tr>
<td>7 6</td>
</tr>
</tbody>
</table>

The great feature of the 16 & 17 Vict. cap. 59, was the reduction of receipt stamps for all sums amounting to 40s. and upwards to an uniform rate of 1d. The stamp may be either impressed or affixed, but must be cancelled by the signature, and a penalty of 10s. is imposed for neglecting or refusing to give such a stamp with a receipt. The other provisions were—that indentures or covenants for an apprentice, clerk, &c., where no money was paid, was fixed at 26s. 6d.; deeds of conveyances for drawbacks or bounties, 1s. if not exceeding 10l., 2s. 6d. above 10l. and not exceeding 50l., 5s. if above 50l.; drafting deeds or papers for payment of money on demand, 1d. (bankers' cheques and letters of credit sent abroad were exempt by the Act; but now, May 1858, a bill is passing through Parliament, by which all bankers' cheques are to be a penny stamp); policies of assurance, 6d. on every 50l. up to 1000l., 1s. for every additional 1000l., up to 1000l., and 10s. for every additional 1000l. (the fractional parts in each case carry the additional stamp). By cap. 63 the stamp on articles of attorney's clerk was reduced from 120l. to 60l.; attorneys and conveyancers are now charged 1d. for every conveyance, and also the conveyance duties on feus-rents in Scotland.

The 17 & 18 Vict. c. 63, is for altering certain Stamp Duties, the effect of which is sufficiently shown by the new scale given in the schedule, which we subjoin. It is only necessary further to give the more material enactments set
indicated in the schedule. By § 4, bills purporting to be drawn abroad are to be so deemed, though drawn in the United Kingdom, and are chargeable with duty accordingly; and the holder of a bill drawn out of the United Kingdom (§ 6) is to affix an adhesive stamp of the proper amount before negotiating it, and the neglect to do so, or to cancel the stamp, incurs a penalty of £100. Bills purporting to be drawn in sets (§ 6) must be so drawn under a penalty of £100. Unstamped drafts on bankers (§ 7) are not to be circulated beyond fifteen miles from the place where payable, under a penalty of £50; but drafts (§ 8) lawfully issued unstamped, may be circulated at any distance by affixing and cancelling the proper stamp. Stamps (§ 10) denoting the duty of one penny may be used for receipts or drafts without regard to their special appropriation. All bills, drafts, and notes (§ 15), except Bank of England notes, are rendered liable to the stamp duty. The exemption from the stamp duty (§ 13) of letters acknowledging the receipt of bills, promissory notes, &c., is repealed; but receipts for money paid to the Crown are still exempted, the stamp duty on paywbrookers' licences in Dublin (§ 20) is reduced from £5 to 7½, 10s. Instruments liable to stamp duty (§ 27) are to be admitted in evidence in any criminal proceeding although they be not stamped.

Schedule—Inland bill drafts, exchange, draft, or order for the payment to the bearer, or to order, at any time otherwise than on demand, of any sum of money.

Lease or tack of any lands, tenements, hereditaments, or heritable substance for any term of years exceeding thirty-five, at a yearly rent, with or without a fine, premium, or grant paid for the same, the following duties in respect of such yearly rent:

If the Term shall not exceed 10 years.
If the Term shall exceed 10 years and not exceed 100 years.
Where the yearly rent shall not exceed £5.
Where it shall exceed £5 and not exceed £10.
Where it shall exceed £10 and not exceed £20.
Where it shall exceed £20 and not exceed £30.
Where it shall exceed £30 and not exceed £50.
Where it shall exceed £50 and not exceed £100.
Where it shall exceed £100 and not exceed £200.
Where it shall exceed £200 and not exceed £500.
Where it shall exceed £500 and not exceed £1,000.
Where it shall exceed £1,000 and not exceed £2,000.
Where it shall exceed £2,000 and not exceed £5,000.
Where it shall exceed £5,000 and not exceed £10,000.
Where it shall exceed £10,000 and not exceed £20,000.
Where it shall exceed £20,000 and not exceed £50,000.
Where it shall exceed £50,000 and not exceed £100,000.
Where it shall exceed £100,000 and not exceed £200,000.
Where it shall exceed £200,000.
Where it shall exceed £500,000.
Where it shall exceed £1,000,000.
Where it shall exceed £2,000,000.
Where it shall exceed £5,000,000.
Where it shall exceed £10,000,000.
Where it shall exceed £20,000,000.
Where it shall exceed £50,000,000.
Where it shall exceed £100,000,000.
Where it shall exceed £200,000,000.
Where it shall exceed £500,000,000.
Where it shall exceed £1,000,000,000.

And where any such lease or tack as aforesaid shall be granted in consideration of a fine, premium, or grant, and also of a yearly rent, such lease or tack shall be chargeable also, in respect of such fine, premium, or grant, with the ad e facade stamp duties granted under the head or title of "conveyance" in the schedule annexed to the Act passed in the 13 & 14 Vict. c. 97.

Exemption,—Any lease made in pursuance of the Trinity College, Dublin, Leasing and Perpetuity Act, 1851.

Conveyance of any kind or description whatsoever in England or Ireland, and charter, disposition, or contract containing the first original constitution of fen and ground annual rights in Scotland (not being a lease, except for the life of the person entitled to the same), in consideration of an annual sum payable in perpetuity or for any indefinite period, whether for farm or other rent, feu duty, ground annual, or otherwise. The same duties as on a lease or tack for terms exceeding 100 years, at a yearly rent equal to such annual sum.

Exemptions.—Any lease or tack for a life or lives not exceeding three, or for a term of years determinable with a life or lives not exceeding three, by whomsoever granted; and any grant in fee simple or in perpetuity, made in Ireland, in pursuance of the Renewable Leasehold Conversion Act, or in pursuance of the Trinity College (Dublin) Leasing and Perpetuity Act, 1851; all which said leases or tacks and grants respectively shall be chargeable with the stamp duties to subject to which the same were subject and liable before the passing of the Act 18 & 17 Vict. c. 63.

Every such lease or tack, and every such conveyance, charter, disposition, or contract as aforesaid hereby charged with duty, and the duties of counterpart thereof respectively, shall be chargeable with the respective stamp duties granted and made payable under the several heads or titles of "Diplotype or Counterpart," and "Progressive Duty," in the schedule annexed to the 13 & 14 Vict. c. 97.

License to demesne copyhold lands, tenements, or hereditaments, or the memorandum thereof if granted out of court, and the copy of court roll of any such licence if granted in court.

Where the clear yearly value of the estate to be demised shall be expressed in such licence and shall not exceed £70. The same duty as on a lease at a yearly rent equal to such yearly value, under the Act of the 13 & 14 Vict. c. 97.

And in leases or tacks, 10s.

STANDARD MEASURE, WEIGHT, &c. The imperial standard yard, and standard pound troy having been de-
STANLEY, REV. EDWARD, D.D., Bishop of Norwich, was born in London on the 1st of January 1779. He was the second son and seventh child of Sir John Thomas Stanley, Bart., of Alderley Park, Cheshire, by Mary, daughter and heiress of Hugh Owen, Esq. of Pencroes in Anglesea. His elder brother, who inherited the manor and estate on his father's death in 1789, was given the title of Berch of Alderley. In his boyhood the future bishop had a passion for the sea and would have preferred the navy to any other profession. Being destined for the Church however he was sent, in 1798, after a desultory education at various schools, to St. John's College, Cambridge; and here in 1802, he graduated B.A. and was 16th Wrangler of his year. He took the degree of M.A. in 1805. In that year, having meanwhile travelled on the Continent and having made a tour in France, during which he visited the Lyceum of Diderot, which was presented by his father to the family living of Alderley. In 1810 he married Catherine, eldest daughter of the Rev. Oswald Leycester, rector of Stoke-nan-Trent, Shropshire. He was rector of Alderley for six years (1805-37) during which he discharged his duties in a manner so conscientious and so thorough as to gain the affection of all his parishioners in an unusual degree. He worked assiduously among the population of his parish—white and black, pure and mixed. He was a man of purely clerical duties, he did everything in his power, by encouraging schools and the like, to promote the intellectual and secular welfare of his parishioners. For the use of the young in his parish he prepared 'A Series of Questions in the Bible' which was published in 1815. Inheriting Whig principles from his family, he was noted at this time for great liberality and toleration in his ecclesiastical opinions; though the zeal and the warm-heartedness of his Christianity were unfeigned. It was perhaps his slight interest in matters of purely theological controversy that inclined him at this time to the quiet pursuit of natural history. Using the opportunities afforded him by his position as the clergyman of a rural parish, he gratified his tastes in this direction by becoming acquainted with the geology, the mineralogy, the botany, the entomology, and the ornithology of his parish. He became a contributor on topics of natural history, and on kindred topics, to 'Blackwood's Magazine' and 'Clerical Magazine'; and 'Blackwood,' entitled 'Adventures on the Alps in the Mauvais Pas' is supposed to have suggested to Scott the opening scene in his 'Anne of Geierstein.' The department of natural history which he principally cultivated was the geology. He was a member, and, for a time the author of the Society for Promoting Christian Knowledge, his well-known work in two volumes entitled 'A Familiar History of Birds, their Nature, Habits, and Instincts. He had already lectured on subjects of natural history to one or two Mechanics Institutions in the north of England, and in 1836 he was Vice-President of the British Association. He was also a Fellow of the Royal Society and President of the Literary Society. Though obstreperous in obtruding his politics on his parishioners, he had taken part on the liberal side on some of the questions of the day relating to the Church. In 1829 he had published 'A Few Words in favour of our Roman Catholic Brethren,' advocating Roman Catholic Emancipations; and in 1835 he published 'A Few Notes on Religion and Education in Ireland.' The spirit abounding in these pamphlets, taken along with his excellent character, and his family-connections, secured him to the Whig government as a suitable man for a bishopric. The long vacancy of the see of Norwich by the death of Bishop Bathurst in 1837, Lord Melbourne offered the bishopric to Dr. Stanley. It was with much reluctance that he quitted the parish where he had lived for so long, and accepted the prebend; with which was cojoined the appointment of Clerk of the Closet of the Chapel Royal. Having accepted the office, however, he set himself with great zeal and punctuality to its duties. Seldom has there been a more hardworking bishop, or one more sanguine in all schemes of improvement. He abandoned his pursuit of natural history and devoted himself exclusively to diocesan business. As the previous bishop had lived to the age of ninety-three, there were necessarily great abuses in the diocese—abuses of which he drew attention to, and, in the manner which he himself to reform with a boldness, which, though successful in the end, aroused much bad feeling against him. As in the House of Lords and elsewhere, where public questions were discussed, he always took what was called The Liberal side of an argument.
Essays," not published till 1810, which he expanded in 1811-19 into three volumes of a 'Handbuch der Ornithologie.' On returning to Denmark in 1802, he excited considerable attention by his lectures; but as he experienced some coldness from influential persons, he accepted in 1804 a call from the University of Jutland, where he remained until 1811. A great part of his works were published (in 1806) his "Grundriss der philosophischen Naturwissenschaft" ('Fundamental Features of Philosophical Natural Science'). The years 1807-9 he spent with his friends in Holstein. He then returned to Halle, and took an extensive part in the preparation of the secret preparations of the Prussian patriots to cast off the French yoke, which they felt to be alike burdensome and disgraceful. When the time for action arrived, Steffen was just beginning to study entomology. The patriotic Addresses roused and supported the energy of his comrades, with whom he continued till the entry into Paris in 1813. After this he returned to Breslau, where he had been created professor of physics and of natural history. These offices he held till 1815, when he removed in a similar capacity to the University of Berlin, in which city he died on February 13, 1845. While in Breslau he wrote, in connection with what may be called his professional pursuits, he published his "Leipziger Verhandlungen für die naturwissenschaftlichen und allgemeinen deutsche gelehrten Anzeigen", an elaborate treatise on entomology, his "Philosophische Studien der Philosophie der Geschichtsphilosophie", a sequel to his 1836; but these works rather represent the philosophy of the Schelling school than add to our knowledge by any new facts. The intellectual activity and mental riches of Steffen however were not confined to one branch of knowledge, and he was often engaged in the thoughts and feelings of his fellow-countrymen. To this description of works belong his essay 'Ueber die Idee der Universitäten' ('On the Ideas of the Universities'), 1807; 'Die gegenwärtige Staatsaufgaben', 1810; 'The present Time, and how it became', 1817; and 'Ueber geheime Verbindungen auf Universitäten' ('On the secret Societies of the Universities'), 1835. His disinclination also to the attempted church union in Prussia rendered him at first the leader of a considerable number of dissenters from that union, and at length involved him in many controversies, which ultimately occasioned the production of his work 'Von der falschen Theologie und dem wahren Glauben' ('On the False Theology and the True Faith'), in 1834, of which more than one edition has been called for. In 1831 he published 'Wie ich wieder Lutherer wurde und war mir das Lutherthum ist' ('How I became again a Lutheran, and what Lutheranism is to me'), which is a personal confession of his conscientious belief in the Christianity of the fathers. In 1837 he also stepped into a new line: he began a series of novels, of which the first 'Die Familien Walseth und Leith,' in three volumes, was followed in 1836 by 'Die vier Norweger,' in six volumes, and that by 'Malcolm' in two. These novels contain many references to himself both in the incidents and opinions, but they also contain well-defined pictures of the peculiarities of national character, narratives of the historical events of the period, with lively and correct descriptions of scenery, experiences in the life of a countryman, with the feelings, even with the passions, and all are penetrated with a deep-lying religious feeling, which give them a peculiar character. In the last years of his life he occupied himself with writing a detailed autobiography, 'Was ich erlebt,' published in ten volumes, from 1840 to 1845. It is perhaps too minute, but contains many interesting facts, and a fragment of it has been translated into English under the title of 'Adventures on the Road to Paris,' an account of the advance of the allied armies in 1814. Several of his writings have been published, 'Nachgelassene Schriften,' with a preface by Schelling.

**STELLITTE.** [Age: 70; born Breslau, Prussia, 1779; died 1859.]

**FRANCIS,** a distinguished British entomologist, was born at Shoreham, Sussex, on the 16th of September 1792. He was for many years a clerk in the Admiralty Office in Somerset House. Whilst holding this position he devoted his leisure hours to the study of natural history, and was a remarkable example of the knowledge that may be gained by the cultivation of the small portion of time allotted for rest in a government office. In the course of a long life he made one of the most complete collections of British insects extant. This collection was the admiration of many entomologists, and was presented to the British Museum by his great friend, Mr. Stephens's taste for entomology led early to the establishment of a collection in the British Museum, where he assisted Dr. Leach in commencing the present collection of insects in that institution. The literature of entomology is largely indebted for its present state to the laborious industry of his illustrations of British Entomology,' which was produced in parts and published from the end of 1792. In addition to this splendid work, he published several papers on entomological subjects, which appeared in the 'Transactions of the Entomological Society.' He was also engaged at the time of his death in writing a catalogue of the British Lepidoptera in the collections of the British Museum. He also published separately 'The Systematic Catalogue of British Insects,' and 'A Manual of the British Coleoptera.' Although distinguished for an extensive, yet his interest in all branches of natural history, and was the author of the 'Wonders of Shaw's Zoology' comprising an account of the Birds, published in 1837. He was a fellow of the Linnean Society, and president of the Entomological Society. He died on the third of October, at his residence at King's Lynn, after a few days' illness, of inflammation of the lungs.

**STEPHENSON, GEORGE,** the inventor of the locomotive steam-engine, was the son of Robert Stephenson and Rachel Carr, and was born June 9th, 1781, at Wylam, a village in Northumberland, where he was a fireman at a colliery; he afterwards removed to Dewley Burn in the same county, where George's first employment was to herd cows, occupying his leisure in modelling clay models of machines and vessels. He was soon called to be employed about the colliery, during which time he displayed a great affection for birds and animals, particularly rabbits, of which he acquired the reputation of having a fine breed. At fourteen years of age he was appointed assistant-firman to his father, who soon after removed to another colliery at Jolly's Close, where George, then only fifteen, was engaged as firman to an engine in the neighbourhood. Ambitions of becoming an efficient workman, he strove to attain a thorough knowledge of the engine, and he succeeded so well that at seventeen he was promoted to be a 'plumgar,' whose duty it was to see that the engine was in proper working condition, and that the pumps drew water effectually; repairing such accidental defects as might arise in the engine. The workman was employed in the construction, and at his leisure hours he would take the machinery to pieces, that he might the better understand it. His father, who had six children, of whom George was the oldest, had been unable to give them any education. In youth by example a sound foundation of good principles and morals had been laid, and at eighteen, whilst employed for twelve hours a day in his labours, and earning only twelve shillings a week, George Stephenson commenced a course of self-education. He attended a small night-school at Walton, where in a year he learnt to read, and to write his own name, for which instruction he paid threepence a week. He next, in 1799, placed himself under a Scotchman named Robertson, at Newburn, who for fourpence a week taught him arithmetic, which he soon learnt, and also taught him a facility for writing. Twenty years he had been advanced to the superior office of brakesman, with increased wages, to which he added, in his leisure hours, by learning to make and mend shoes. At that time he was a big, raw-boned fellow, with strong hands, and strength and activity at the village feasts, but remarkable for his temperance, sobriety, industry, and good-temper, yet on one occasion he fought a bully who would have oppressed him, and his victory on that occasion secured him ever after from repetition.

When by the most rigid economy Stephenson had saved sufficient money to furnish a small house, he determined to settle, and on the 26th of November 1806 he married Fanny Anderson, the daughter of Mr. John Anderson, of Leith, Edinburgh. Robert Stephenson had been appointed brakesman to the engine employed for lifting the ballast brought by the return collier ships to Newcasle. In his new abode at the Bullet Hills, he continued to occupy himself with mechanical experiments, expending
but it was found to be unmanageable. Sir Humphry Davy was invited to attempt something; for which purpose he visited Newcastle in August 1816, and on November 9 of that year he read a paper on the construction of his third lamp before the Royal Society of London. Mr. Stephenson was at the same time occupied on the same subject. In August he made a drawing for a lamp, which on October 21, 1815, had been made and tested; a second and a third lamp were also invented to contain the amount of light; and on November 30, of that year, before he could by any possibility have heard of Davy's invention, his third lamp was finished and tried in Killingworth pit, where it was found to be more efficient than that of his competitor. No controversy has arisen, into which we shall not enter, as to priority of invention. There is, however, every reason to believe that Stephenson invented his lamp long before and had tried it a few days previous to Davy having announced his discovery; and the natural conclusion is, that he was effectually by the want of a safety-lamp, and reasoning from the same facts, the inventors arrived at the results independently of each other; for the two lamps, although different in construction, were based on identical principles, but arrived at by different trains of thought.

We cannot attempt to trace all the improvements in details which Mr. Stephenson introduced in the locomotive, but be very early perceived that, for its proper working, the engines must be provided with a sufficient steam for raising the regular level were essential requisites. Very little attention had hitherto been paid to this, and the tramroads were carelessly laid out and not kept in good repair. In 1816 therefore he took out a patent for an improved form of rail and tramroad, with engines to be placed at intervals, on one of which was placing it on springs, and they were attended with marked success.

The construction of railroads had for some time occupied much the public attention. In 1819 the engineer of the Colliery, dreading the turn their tramroad into a railway, employed Mr. Stephenson in its construction. The length was about eight miles, and being over a hilly country, he took advantage of the heights to form self-acting inclines, the length and number of which were more than doubled. In November 1822 it was opened for traffic. He was next employed to construct the Stockton and Darlington line, for which an act of parliament was obtained by Mr. Pease in 1825, to be worked "with men and horses, or otherwise." The proprietors had agreed, on his recommendation, to make the line as a railroad and not as a tramroad, with stationary engines for the steep gradients, but horse-power was to be used for the levels, for Mr. Stephenson's confident anticipations of the success of the line had been so much increased by the events of 1822.

He began the work in May 1822, but in 1823 an amended Act being procured for working the line with locomotives, Mr. Stephenson was appointed resident engineer at a salary of 300l. per annum, and upon that appointment a complaint was made that he had contrived the tramroad, which was not true. He remained on the line, however, until September, 1825, and an engine driven by Mr. Stephenson himself drew a load of ninety tons at the rate of upwards of eight miles an hour. It proved highly remunerative, for besides a far larger amount of goods traffic than had been calculated on, a passenger traffic arose that had been wholly unthought of; the passengers however were for a time conveyed in carriages drawn by a horse at a speed of ten miles an hour. It may be mentioned, that this railway has created the town and port of Stockton-on-Tees, then the site of a farm, but now containing 15,000 inhabitants.

In 1824, while the Darlington line was in progress, Mr. Stephenson, feeling the difficulty he had experienced in constructing his engines in a blacksmith's shop, proposed to Mr. Pease of Darlington, his firm friend and great patron, the establishment of an engine-factory at Newcastle. The proposal was adopted, and for a considerable time it was the only manufactory for locomotives in the kingdom. It is now incorporated with the Darlington engine-works, and he has been the training-school, whence he issued a vast number of skilled workmen and eminent practical engineers.

In 1824 the project of a railway or tramroad between Liverpool and Manchester began to be agitated. Increasedparalleled are enormous, but there was much controversy as to the means. At length a railway was decided on, Mr. Stephenson was employed to conduct the survey, and application was made to Parliament for an Act. A strong opposition was raised both within the House of Commons and without. Landowners drove
engineers off their grounds, and before the Committee the most absurd objections were urged against the whole scheme, the idea of any quick transit being a subject for especial ridicule. The Bill was however carried on a second application, and Mr. Stephenson was appointed principal engineer. The work was commenced in June 1829, and after struggling through many difficulties—one, and not the least, being the carrying the railway over Chal Moss—it was opened on Sept. 15, 1830. During its progress eminent engineers had rendered invaluable services by their advice and counsel, recommending horse traction; but at length Mr. Stephenson prevailed on the Directors to offer a prize for a locomotive engine, conforming to certain conditions, which was done, and in consequence of a prize was won by the Rocket engine, in the construction of which he had availed himself of the assistance of his son Robert.

From this moment his fortune was made. Employment of a most remunerative character poured in from all sides. Railways were projected in every direction, and he became the chief engineer of several of them. With these he was incessantly engaged till 1840, when he resigned most of them, and settled at Tapot in Durhamshire, where he commenced a fresh pursuit in working the Clay Cross collieries. At this time, however, the application of the scientific principles of mechanics to the improvement of railways had much increased, and many improvements in every part of the system, however, during however continued unabated, and he took an active part, either as engineer, chairman, or shareholder, in the Whitehaven and Maryport, the Yarmouth and Norwich, and the Newcastle and Edinburgh East Coast Line, with won of his partners and associates, as also at his own expense, Newcastle (designed by his son), was connected; he was one of the committee of management, but he did not live to see it completed. He was also employed in Belgium, and he travelled into Spain to inspect a proposed line from the Pyrenees to Madrid, but his work was from then on. On his return from Spain in 1845 he relinquished still more his attention to railway matters, and occupied himself almost entirely with his collieries and lime-works, with the cultivation of his farm and gardens, and indulged in his old favorite for keeping birds and animals. With the exception of promoting the Ambergate and Manchester Railway, inventing a new self-acting brake, of attending the ceremony of opening the Trent Valley Railway (when Sir Robert Peel made a speech complimentary to him), and of being considerably troubled by applications for assistance and advice from projects and inventors of all kinds, to whom however he was invariably attentive and kind, he passed the remainder of his days in the quiet and retirement that he desired, and great interest in the Institution of Mechanical Engineers of Birmingham, which he had founded, and was President of. He died after an short illness on August 12, 1848, leaving a name rendered illustrious by the patient perseverance of a high and noble spirit, taken certain shape and form in the hands of a remarkable genius. A valuable biography of this eminent man has been written by Mr. S. Smiles, to which we are indebted for many of the facts in this notice.

STEREOSCOPE, from survey (solid) and survey (view), an instrument by which two pictures of any object, taken from different points of view, are seen as a single picture of that object, having the natural appearance of relief or solidity.

A single picture may be seen with two eyes, yet that only a single representation of the object is presented to the mind, most of course have very early forced itself on the consideration of men of attentive and reflective habits. And it could not fail to be observed that the appearance which an object—a statue or a vase for instance—presents when looked at steadily, and with only one eye, is different from that which it presents if it be then looked at, without changing the position or moving the head, by the other eye alone. Accordingly we find in some of the earlier as well as the later Greek writers, and in some of the Roman, a distinction made between the object, and the subject, and speculations as to the cause. Euclid showed, of course, that a sphere in which each eye sees the same representation of an object; and Olen some centuries later explains his idea in the same way; but similar pictures are not seen at the same instant but successively, and that these rapidly succeeding pictures produce on the mind the impression which is concurred of the object. At the end of the 18th century, Leonardo da Vinci, and in the 19th and following centuries, Baptista Porta and Aglinonius, wrote on the subject of vision as produced by dissimilar pictures seen by each eye; but down to our own time natural philosophers have been almost universally content to adopt the opinion that the only eyes work at one time. The whole question of vision by a single eye, and of monocular and binocular vision, was reopened by Mr. Wheatstone—to whom the world is indebted for the application of electricity to telegraphic purposes—in a paper entitled 'Conjunction of the Views of Objects, and of the Part of the Field of Vision by One Eye' (1838).

Some Remarks and hitherto Unobserved Phenomena of Binocular Vision,' read before the Royal Society, June 21st, 1838, and again, before the British Association at Newcastle, in the following August, and printed in the Philosophical Transactions of the Royal Society, months later.

In this paper Mr. Wheatstone argued that the appearance of relief and solidity which we obtain in looking at objects in nature, arises from these being a dissimilar picture of the object, projected simultaneously on the retinae of each eye; and, it is the optic axes of which are not parallel; whereas in viewing a pictorial representation two similar pictures are projected on the retinae, and hence the resultant flatness. It is not necessary to enter further upon his views, nor upon the whole, for as speaking of it. He only showed that a picture treated with fully of the head sounds, vol. xxi., p. 404-6. Mr. Wheatstone sought to elucidate and confirm his theory by an ingenious instrument which he exhibited when he read his paper, called the Stereoscope. This instrument, now known as the Refracting Stereoscope, consists of two plane mirrors, fixed with their backs to each other at an angle of 90 degrees. These mirrors (or polished glass prisms) are supported on a central stand, which is fixed in place, and a mahogany framework, which has two windows to support the two pictures (which have been taken from dissimilar points of view) in the same horizontal line, parallel to each other and at equal distances, one on each side of the mirrors, The observer, by placing his eyes as close as he could to the windows, the angle of the mid-line of his face and forehead, sees the two dissimilar pictures united, so as to give the appearance of the object represented, not as it is seen depicted on a plane surface, but with all the solidity, which object in itself, the reflecting stereoscope excited great interest among scientific men when first exhibited, but the pictures prepared for it were almost exclusively dissimilar outlines of various geometrical solids—photography not being then in existence—and by those who did not employ it for a purely scientific purpose it soon came to be regarded as merely an ingenious and somewhat ornamental as well as expensive optical toy. For most purposes it has been superseded by the more convenient Refracting Stereoscope.

For the Refracting Stereoscope we are indebted to the inventor of another very beautiful contrivance, the Kaldioskope (KLEIDOSKOPE), S. L. 1832. Sir David Brewster having in 1832 prosecuted an elaborate series of experiments with a view to the establishment of what he regarded as the more correct theory of binocular vision, and some of these experiments led him to construct the instrument which, in the form it actually assemblled, he called the Lenticular Stereoscope. He early exhibited his instrument in his classes at Aulends's but he first fully explained his views on binocular vision, and made public his invention, in a paper 'On the Law of Visible Position in固体 of the Representation of Solid Figures by the notion of Dissimilar Plane Figures on the Retina,' which he communicated to the Royal Society of Edinburgh in January 1843. He further explained and defended his views in many subsequent papers, which, like the former, appeared in the Edinburgh Philosophical Transactions, of that and following years. Of these very valuable contributions to the science of optics it is unnecessary to speak further here, and into the controversy which arose between the author and Mr. Wheatstone on these views, and the theories of binocular vision, the former, as the inventors of the stereoscope, we shall not enter: the opinions of Sir David Brewster, in their manifold and digested form, will be found amply set forth in his work 'The Stereoscope,' 1844, London: Longman, Hurst, and Co., in the paper already referred to, and in another which formed the Bakerian Lecture of the Royal Society for 1839, being 'Part II. of Contributions to the Physiology of Vision, and on Binocular Vision.'
The Lenticular Stereoscope of Sir David Brewster, as described by himself, "consists of a pyramidal box of wood or metal, or any other opaque material, blackened on the inside, and having a lid for the admission of light when the pictures are opaque. The box is opened, in order to look through the right eye, and closed for looking at the pictures when they are transparent. Another lid is sometimes added, so as to open externally on the bottom of the box, for the purpose of exhibiting dissolving views in the stereoscope. The bottom of the box is generally furnished with a ground-roughness, so as to be very fine, or very fine-grained paper may be used. The top of the box consists of two portions, in one of which is the right eye-tube containing a semi-lens, or quarter-lens, and in the other the left eye-tube, also containing a semi-lens or quarter-lens. These portions may be advantageously made to approach or recede, in order to suit eyes at different distances from one another; and the tubes containing the lenses should draw out, in order to suit long and short-sighted eyes." The two dissimilar pictures (which for convenience are mounted on a thick card, forming the universally known "slide") are placed in a groove in the bottom of the box, when, on looking through the eye-tubes, they are seen united into a single picture, and the object or objects, if a proper amount of light is obtained, stand out with an almost magical appearance of relief and solidity. The employment of photography for the stereographs has wonderfully extended the range of the instrument, and now, with the eye-tubes within the hands of the manufacturer, an artist philosopher as an extremely ingenious piece of scientific apparatus, or have found a somewhat larger though less important circle of admirers as an elegant toy, has become one of the most widely known and universally popular means of amusement, and the rank and the rapidity of its development, as a serious means of instruction, is by means of these semi-lenses that the stereoscopic effect is produced, though they do not themselves produce that effect. What they accomplish is the transference of the two dissimilar pictures or stereographs to a middle point. The union of these two pictures, or their superposition on that middle point, produces the stereoscopic effect. The semi-lenses are the two halves of a convex lens, so placed that the edge or thin part of each is turned inwards— the opposite direction that is, to that which it held in its original position. How this acts may be understood by a very simple experiment. If any small object as a coin or medal be laid on a piece of white paper and looked at with the right eye only, through a convex lens, the right half of which is covered by an opaque substance, the coin will be seen some distance on the left of it, behind the glass, but still distinctly visible, for the eye be held close to the lens, and the proper focal distance be chosen. On turning the lens so that the left half is covered, and looking through the uncoated half with the left eye only, the coin will be seen at a distance on the right side of its true position. Just so the half right of a picture or plate of the stereoscope—which are placed 1½ inches apart, corresponding to the distance between the eyes— make the two pictures in the instrument to approach and become superimposed on each other. But as the pictures are slightly dissimilar, having been taken from points of view correspondent to those of the right and the left eye respectively—and as, consequently, that portion of the right side of all solid objects which the right eye sees is represented in one picture, and that portion of the left side which the left eye sees is represented in another, as well as the front which is common to both eyes, it follows that when these pictures are superimposed, the resultant single picture includes all that each eye sees, and therefore has all the apparent roundness, solidity, and relief which the original presented when looked at with both eyes; an effect aided it must be confessed by the isolation of the pictures in the chamber of the stereoscope. Various modifications have been made in the instrument—as the employment of larger lenses, the changing the size of the images formed, the reduction of the forms, &c.; but the principle is the same in all, and some of the changes are certainly not improvements.

From what has been said, an attentive reader will have no difficulty in understanding that the stereoscopic picture must depend mainly on the character of the dissimilar pictures or stereographs. This is most certainly the case, though too often overlooked or insufficiently regarded by those who take stereoscopic pictures. Stereoscopic portraits are usually taken with cameras contrived for the purpose. In order to take stereographs of landscapes, buildings, statues, &c., the ordinary landscape camera is employed; the camera being removed, after the first picture is taken, to a position parallel to that just occupied, and more or less distant from the first position in proportion to the distance from the object to be represented. The stereoscopic angle, as it is called, has been laid down by high authority at 1 in 25 for objects 60 feet or more distant, some have been taken as close as 100 feet, and they are much less distant from the first position in order to take views of an object only 20 feet distance. But the effect of such an arrangement is obviously to make one picture represent much more of the right side, the other more of the left side of the object. It would be seen by a person standing, say midway, between the two positions. And the two pictures so taken must, when united in the stereoscope, present an exaggerated and therefore untrue representation. In fact there will be, what is so commonly seen in the stereoscope, an unnatural appearance of separation between the chief object and the accessories. You see round the figure in fact, just as in life you see round a statuette or small model, and hence there arises that detached model-like appearance which is so often, and very improperly, objected to stereoscopic representations. What the stereoscope ought to show is, the representation of an object or objects in nearly the same relative solidity, relief, and separation as in life. The fragments of the historical and civil history must be ready to be exhibited if the stereographs were taken, as they ought to be, and as the most successful (though not the most popular) are taken, from positions little if at all exceeding that of the eyes apart. The great importance of strict accuracy in view of the vast range of subjects and objects that may be produced by this means of antiquities, objects of special scientific interest, &c., will be at once acknowledged; and the value of the stereoscope for affording such representations in their greatest attainable perfection is daily becoming more apparent. It will be enough to allude, as illustrating this, to the recently published views in Egypt, in which the antiques and the scenery of that country are almost literally brought home to those who cannot go to them; and to the very remarkable series of stereographs of the Peak of Teneriffe, published by Mr. Piani Smyth, in his recent work, 'Teneriffe, an Astronomer's Experiment,' which gives us almost the very cone itself, in some of its most striking and characteristic phases, to gaze upon and to study.

STERLING, JOHN, was born at Kaimes Castle, in the island of Bute, Scotland, on the 20th of July 1806. Both his parents were Irish by birth, though of Scottish descent; and his father, Edward Sterling (afterwards well known as a collector and dealer in paintings), was a schoolmaster, and, in pursuing the occupation of a gentleman-farmer, after having been educated for the Irish bar, and having served for some time as a captain in the army) had rented Kaimes Castle a short time before his son's birth. John was the second son of the family. He was a bright child, but a very boy, leaving only himself and an elder brother. In 1809, the family removed to Llanheathin, in Glamorganshire, Wales; and here John Sterling received his first school-education. His father about this time began to contribute to the 'Times' as an occasional correspondent; and the interest he thus took in politics, led him, on the peace of 1814, to remove again with his family to Paris. Driven from Paris by the return of Napoleon in 1815, he then went to Switzerland, and from thence to England, where he settled in London, where gradually the father rose to his eminent position in the world of politics and journalism. He was destined to outlive his son.

After having been at various schools in or near London, Sterling was sent to the University of Glasgow; whence, after a brief stay, he was removed in 1824 to Trinity College, Cambridge. Here Julius Hare, afterwards Archdeacon of Lewes, was his tutor, and here he formed the acquaintance of William Wordsworth, John Stuart Mill, and others. In 1827 he left Cambridge altogether.
without taking his degree. In 1828 the "Athenaeum," then recently started by Mr. Silk Buckingham, was purchased by Sterling, or at his instance, and he and Maurice conducted it and wrote in it for some time. The speculation however in their hands did not answer commercially, and the journal was sold to its present proprietor. Sterling, to whom it was not easy to part with, declared that he would not be engaged in any employment for his living, continued to reside in London, the centre of a circle of ardent and thoughtful young men, including not only his college friends, but such additions as John Stuart Mill, who was eager to learn and to be Coleridge's characteristic. It was about the year 1829 that he first became acquainted with Coleridge, then living his recuse life at Highgate; and Coleridge's influence on Sterling was great and enduring. It was evident in a three volume novel, entitled "Time and Chance," which he published in 1834, but which was not published till a year or two later. In November 1830 he married; and shortly after, being in ill-health, he and his wife went to the West Ijssel-Staad of St. Vincent, where a valuable sugar estate had been bequeathed to him, his elder brother, and a cousin, by one of his mother's uncles. He stayed about fifteen months in St. Vincent, returning to England in August 1832. In the spring of 1833 his novel was published, but obtained little recognition except from Sterling. The latter, then his tutor, the Rev. Julius Hare, at Bourn, the effect of their conversation on Sterling's mind, then vibrating under the prior influence of Coleridge, was that he resolved to take holy orders in the English Church. He became curate of Chichester on Trinity Sunday, 1834, and immediately became curate of Hurstmonceaux in Sussex, where his friend was rector.

Sterling abandoned his curacy on eight months, residing it in 1835, on account of his ill-health. It is improbable that at the same time there was a change, or a tendency to change, in his opinions. From this time, at all events, there was a gradual divergence in his views from the fixed creed of the Church of England, though his relations to men and objects did not change principle, as is evident from the great oratio he delivered in the University of Cambridge, in which he spoke of the "bestowal of the scriptures" as the "desired of all nations," and of the "fulfillment of the dispensation of the old covenant." He was thus an Evangelical, as he was to be always, but one who looked to a different and more distant future than his contemporaries. He had been with his brother, Mr. Thomas Carlyle, in Paris, where he had projected the mode of improving the illumination of lighthouses by the substitution of oil lamps with parabolic mirrors for the open coal-fires. When that gentleman was appointed engineer to the Northern Lighthouse Commissioners, he made it his first tour of inspection, and afterwards introduced a still greater improvement in the illumination of lighthouses by means of the cast-iron lamps. This new system he deemed to distinguish one lighthouse from another. In 1807, an Act having been obtained in the previous year, he commenced the construction of the Bell Rock Lighthouse, on a rock in the North Sea, a few miles off Arbroath in Forfarshire, on which the light was exhibited for the first time on Feb. 1, 1811. The rock being extremely small, and almost entirely covered, even at low-water, except in spring-tides, offered great obstacles to the construction, but they were successfully overcome, and the work, which was turned over to the National Lighthouse Commissioners, was completed. It was constructed with plates, was published at Edinburgh in 1834. A controversy has arisen as to the originality of Mr. Stevenson's plan, into which we cannot enter, but it is certain that the general principle of the "scopic" or invisible lighthouse is an old one, and was first exhibited in its perfection about 1785, and was only recently applied to secure a firm and enduring foundation, and this was undoubtedly done by Mr. Stevenson. In 1814, on another tour of inspection, Sir Walter Scott was a companion of the engineer and commissioners in the voyage, which afforded many materials for descriptions in Scott's poem of "The Lord of the Isles," and in the novel of 'The Pirate.' Mr. Stevenson held the situation of engineer till 1842, during which time he erected no fewer than 23 lighthouses. He was also employed in numerous engineering works in various parts of the United Kingdom, but chiefly in Scotland, in connection with the improvement of rivers and harbours, and the erection of piers and bridges, into which latter class of works he introduced some new principles of construction, which were likewise executed on the north of England and Glasgow, which, though not adopted, was admitted to be extremely clever. He was employed to report on other lines of railway, and he suggested the use of malleable iron rails instead of the cast-iron rails and tramplates previously in use. In 1836 he became a member of the Institution of Civil Engineers, and while he lived was looked upon as an authority of great weight on all questions connected with the improvements of ports, harbours, and rivers. He died on the 27th of July 1849, and was succeeded by Mr. F. R. M. Lock, who was the last engineer of the Northern Lighthouses, and who was appointed on the death of Mr. Stevenson.
STOCKS, [MATTHIA].

STOCKS, JOHN E., M.D., was born in 1832. He was educated for the medical profession at University College, London. Here he distinguished himself in his classes, and especially for the accuracy and Completeness of the answers which he gave to the questions which were put in the examination rooms. He obtained an appointment in the East India Company's service, and soon distinguished himself for his acquaintance with plants. He was sent to Sind and Beluchistan to report on the vegetable productions of the country, and in a succinct and comprehensive manner. He came back to England about the year 1854, intending to work up his numerous materials for publication. His health however failed him, and after having deposited his collections at Kew, he retired to Burton-on-Trent, near Burton, in September 1854.

STOCKTON. [CALIFORNIA, 2.]

STODDART, SIR JOHN, knight, was born in 1773 in the parish of St. James's, Westminster, but his father, who was a lieutenant in the navy, residing in Wiltshire, he received his early education in the grammar-school at Salisbury under Dr. Skinner. His proficiency in Greek at this school occasioned his being sent to the University of Oxford, where he was entered at Christchurch College in 1790, and graduated as B.A. in 1794. He at first studied divinity, but feeling an inclination for the law he proceeded B.C.L. in 1796, and D.C.L. in 1801. In the meantime he had neglected general literature, and in 1796 and 1798 he had published translations of Schiller's two dramas of 'Fiesco' and 'Don Carlos,' both with Dr. Noël, of which their initials appeared on the title-page. At this period he took a favourable view of the French revolution, and in 1797 published a translation from the French, entitled, 'The History of the Two Ermas.' It was directed against the principles of the Executive Directory of France, with the Lives of the present Members.' In 1801 he was admitted a member of the College of Advocates, and published Remarks on Local Scenery and Manners in Scotland, during the years 1795 and 1800, in 2 vols. 4to. In 1806, on the recommendation of Sir William Scott, he was appointed king's advocate and admiralty advocate in Malta, in which situation he remained nearly four years, when he returned to England, and resumed his practice in the courts of Doctors' Commons. In 1810 he commenced writing on political subjects in the Times newspaper, his contributions being marked J. B., and this led to his becoming the political editor in 1812. His writings in this paper were distinguished by great energy, the possession of much varied knowledge, a clear style, with a power of fulmination, too often founded on mere prejudice, that occasioned his receiving the sobriquet of Dr. Slop, and as such was buried at George Cruikshank in the parody and satire which was written by Rone. Dr. Stoddart's works were taken by some moderns as he failed in reaching to any greater similarity than that arising from their dislike to the course taken by the French revolution, which, in the doctor's case, displayed itself in the whole course of his public life, that is, as a director of the political policy. He held this important post till the close of 1816, when, as a consequence, it is said, of the disapproval of the proprietors of the continued violence of his attacks on the now imprisoned emperor, his connection with the Times was dissolved, and in 1817 he started an opposition paper called 'The New Times.' It was unsuccessful, and in a short time he left it, retired to private life, and to his practice as an advocate. In 1836 he was appointed chief-justice and judge of the Court of Malta, being knighted at the same time, and in that office he distinguished himself by his able and conscientious manner in which he discharged his duties, until his return to England in 1838. From that time till his death he led a private life, in which he was much and widely esteemed; but occasionally published pamphlets on legal subjects, and took considerable interest in the reform of the law, being one of the earliest members of the Law Amendment Society. He also wrote 'An Introduction to General History,' and a Universal Grammar; or Science of Language, which were prefaced with Memoirs of the Cypriot and Other Metropolitans, but have likewise appeared as separate works. A Statistical, Administrative, and Commercial Chart of the United Kingdom, compiled from parliamentary and other authorities, was another of his productions. He died at Brompton-square, London, on February 16, 1856; and on the first meeting of the Law Amendment Society after his death, Lord Brougham pronounced a warm eulogium on his memory.

STOKE POGES, [BUCKINGHAMSHIRE,]
bonhood of Smyrna.' On the Geology of the Island of Zante—Currents of Sea water running into the Cephalonia—A Personal Sketch of the Geology of the Western Part of Asia Minor,

On the failure of the health of Dr. Buckland, Mr. Strickland was appointed reader in geology in the University of Oxford. His powers of observation on birds are not very numerous. Amongst these the following were published in the 'Proceedings of the Zoological Society':

1. Descriptions of New Species of Birds from West Africa.
2. Notes on a certain Species of Birds from Malacca.
3. Many other papers on birds and their habits.

As a zoologist Mr. Strickland was best known as an ornithologist. He was thoroughly acquainted with the birds inhabiting Great Britain, and gradually extended his knowledge of the forms of these animals. His papers on the classification of birds are not numerous. The following are the titles of some of his publications on the subject:

- 'Descriptions of New Species of Birds from West Africa.'
- 'Notes on a certain Species of Birds from Malacca.'
- 'Many other papers on birds and their habits.'

During his life Mr. Strickland was engaged in preparing a large work on the synonymy of birds, one volume of which has been published since his death.

Mr. Strickland, during his geological researches, had attracted his attention to the mollusca, and numerous papers on the recent and extinct forms of the Mollusca attest his knowledge of this department of natural history. With his great knowledge of the detailed facts of the natural history sciences it is not matter of surprise that he took a deep interest in classification. He proposed at one of the meetings of the British Association for the Advancement of Science the appointment of a committee for the purpose of reforming the nomenclature of natural history.

He entered the army, and which has been extremely useful in establishing clear rules for the nomenclature of zoology.

STURGEON, William, distinguished as an electrician, was born at Whittington, in the county of Lancaster, in 1783. His parents were in humble circumstances, and he was at first apprenticed to a shoemaker; he subsequently entered the militia, and afterwards the Royal Artillery as a private soldier. It was whilst thus engaged that his taste for scientific pursuits commenced, and he employed his leisure hours in making experiments more especially in electricity, and the discovery of galvanism, Arago, and Ampère, in the newly-created sciences of magneto-electricity and electro-magnetism, and was soon enabled to suggest a modification of Ampère's rotatory cylinders. In 1824 he began to publish the result of his researches, and in that year four volumes of his paper on the 'Electricity and Magnetism' were published in the 'Philosophical Magazine.' In 1825 he presented a paper to the Society of Arts which was published in their 'Transactions,' describing a complete set of electro-magnetic apparatus of a novel kind. This apparatus was remarkable for attaining a larger amount of power in a smaller bulk than had been hitherto attained by any other arrangement. For this invention he obtained the large silver medal of the Society of Arts and a purse of thirty guineas.

Soon after the invention of the electro-magnetic machine, Mr. Sturgeon drew attention to the powerful effects to be obtained from the use of soft iron in the construction of the electro-magnetic apparatus. The soft iron horse-shoe magnet that was employed was the constant companion of the electro-magnetic machines since that time. Mr. Sturgeon subsequently directed his attention to the construction of plates for the various kinds of galvanic batteries. In his 'Experimental Researches in Electro-Magnetism, Galvanism,' &c., he directed attention to the superior properties of amalgamated plates of rolled zinc over the unprepared cast zinc before generally used. His method of dipping the zinc plates in acid, and afterwards in mercury, is employed to this day in the majority of galvanic machines. He subsequently suggested many modifications in the form and method of application which are now in daily use, and his name is inseparably connected with the mechanical application of the principles that had been worked out by Oersted, Faraday, and Ampère, since the beginning of the present century. Mr. Sturgeon for some years occupied the chair of Experimental Philosophy in the Hon. East India Company's Military Academy at Addis-
combs. During the latter part of his life he filled the office of Lecturer on Science at the Royal Victoria Gallery of Practical Science at Manchester. He died at Manchester in the month of December, 1850.

STURM, JACQUES CHARLES FRANCOIS, the discoverer of the celebrated theorem which bears his name, was born in the city of Paris on November 25, 1803, and was educated at the College de Jarente, Strasbourg, in the middle of the last century. After completing his school education and his classical studies at the college with remarkable success, he became in his fifteenth year a pupil of the Encyclopedic, where he made rapid progress in the study of mathematics and philosophy. The sudden death of his father, leaving his mother and four children, of whom Charles was the eldest, without any adequate maintenance, compelled him, before the close of the year 1818, to resort to public charities for the support of himself and his family, and three years afterwards he was recommended as tutor to the son of Madame de Stael. At the close of the year 1820 he accompanied his pupil to Paris; and though he shortly afterwards returned to Geneva, he found no sufficient occupation there, and he finally resolved, in company with his intimate friend and school-fellow, M. Colladon—the present distinguished professor of physics at Geneva—to seek his fortune in the French capital. Sturm had already become famous to mathematicians by several articles in the 'Annales des Mathématiques' of M. Gergonne, published at Nimes, on different branches of analysis and geometry, and the stimulating recommendation which he received from M. Lhuillier, and the kind offices of M. Germain, an eminent teacher of mathematics at Paris, made them known to Ampère, Fourier, Arago, and other eminent members of the Institute of Sciences, who recommended them to participate in the 'Memoires pour servir a l'Education des Étrangers,' vol. v., published, agreeably to the very inconvenient usage of the Academy, eleven years afterwards, in 1838.

The determination of the number of real roots of a numerical equation which are included between given limits, is a problem which had occasioned the attention of the greatest analysts of the past age—of Lagrange, of Laplace, and more especially of Fourier, who of all other analysts had made the most remarkable and practical, though he had failed in its theoretical, solution. The attention of Sturm had been for some time directed to this class of researches, which he pursued with remarkable continuity and diligence, encouraged, or at least interested, by the instructions and advice of M. Arago, and of the latter his own professor. This was the discovery of the theorem which will be for ever associated with his name, and which conquered the difficulty that had embarrassed all his predecessors, and thus permanently extended the dominion of analysis. [Sturm's Theorems.]

The memoir which contained this important theorem was presented to the Academy on the 23rd of May, 1829, supplementary papers being read at the following meetings; and immediately, without contest, its author was honored and rewarded for his labors. His connection with the French Academy enabled him to give an immediate account of his method to the world ('Bull. Univ. des Sciences Math. Phys. et Chim.,' vol. xi. p. 416, art. 271, 272, 273). The paper itself was not published till the year 1835, in the 'Mémoires des Savants Étrangers,' vol. vi., where it appears without a date.

In the course of a few years he was chosen a member of the principal scientific societies of Europe: he was elected a member of the Royal Society of London; the Académie was the successor of Ampère in 1836; in the same year he was made Professor of Mathematics at the Collège de Jarente, upon the special recommendation of Arago, at the Collège de Jarente, in 1838, and in 1840 he was appointed to succeed Poisson in the chair of that subject. In 1844 he was elected, by a foreign member of the Royal Society of London, and received the Copley Medal, for his valuable mathematical labours in the solution of a problem which has baffled some of the greatest mathematicians that the world has produced. [The first announcement of the theorem in the English language was not made until 1855, when Professor J. B. Young, of Belfast, inserted the substance of Sturm's memoir in his work entitled 'The General Theory and Solution of Algebraical Equations,' published in that year. The first intimation of it had reached him in the spring of May, 1840, when he had copied out and dispersed a dispassionate comment of Lacroix; he thought the discovery of sufficient importance to justify the destruction of many pages of his manuscript prepared for the printer, and the suspending of the press. 'The theory of Sturm's membrane should be published.' This he received in July, and his own work was published in August. To the appreciation and real of this analyst, whose recognition and promulgation of the value of Sturm's labours were thus both immediate and simultaneous with the publication of his own membrane, himself, were greatly indebted. In the preface to his Mathematical Dissertations' (one of which is devoted to the theorem) dated November 25, 1840—only five days before the presentation of the Copley medal—he adverts to Sturm's discovery as at that time existing considerable interest among analysts, as well in this country as on the continent; and he then expresses his own estimation of it in the following terms; 'I believe that I have already contributed somewhat towards bringing Sturm's work into more conspicuous and more favorable notice in Great Britain, and that it has been sufficiently praised by M. Germain, a former editor of the Academy's Reports, and by M. Lajous, a former writer upon Analysis, as well as by M. Caillet, the editor of the Journal des Mathématiques, and by M. Lacroix, in his Mathematical Dictionary.' In Young's subsequent introductory volume on 'The Analysis and Solution of Cubic and Biquadratic Equations,' published at the beginning of 1842, he invited the attention of the young analyst to the analytic solution of the problem of Sturm's former work on equations,—entitled 'The Theory and Solution of Algebraical Equations of the Higher Orders,'—which appeared early in the following year, is chiefly devoted to the analysis and development of that method and the previous theories of Biquadratic Equations, which were treated as mere applications of his own theory to the determination of the number of roots of the equation.

In France it was not without some difficulty that the substantial rewards of his scientific achievements were obtained; he was a foreigner, and naturally placed at a disadvantage in a contest with national competitors. It is right to consider his not being honorably rewarded both for the honour of France and as a proof of the very high reputation which Sturm had attained. The subsequent memoirs of Sturm, whether first presented to the academy or not, were chiefly printed in the journal of M. Liouville. Two of these memoirs, relating to the discussion of differential and partial differential equations, such as present themselves so commonly in the solution of the more important problems of mathematical physics, possessed a merit so extraordinary and so general, that the academy was at last declared, at a time when he was himself a competitor with Sturm for a place in the Academy, that 'impartial posterity would place them by the side of the finest memoirs of Lagrange.'

Of these two memoirs was presented in 1833 to the concours for the great prize of mathematics, to be awarded by the Academy in 1834 for the most important discovery in that science made known within the preceding three years. The academy conferred the prize on Sturm—not for the memoir which he had submitted to the judgment of the commission, but for that which contained his celebrated theorem and which had been presented in 1829. Other memoirs relate to optics, mechanics, pure analysis, the theory of functions of several variables, the theory of surfaces, the theory of quadratic forms, among other questions which have been treated in those several branches of science. One of the latest of these was a communication to the academy on the theory of vision, and is remarkable both for its geometrical and analytical elegance with which many questions subordinate to the theory are treated in it. It confirms generally,—with one important exception relating to the asserted muscularity of the crystalline lens and the changes attributed to its action,—the views of the late Dr. Young on the action of the lens. Dr. Young, the mathematician, has not been quite satisfied with the impression, as well as the extent of his knowledge as of his inventive power.

The health of M. Sturm, which had previously been remarkably vigorous, began to decline in 1851, probably in...
consequence of his laborsious public employments and the unmitting severity of his studies. He died on the 15th of December 1855, to the deep regret of a large circle of friends and pupils, to whom he appears to have been singularly endeared by the modesty, truthfulness, and simplicity of his character.

STURMIA, a genus of plants belonging to the natural order Orchideae and the tribe Malandreae. It has a petal perianth; lip anterior, erect or oblique, entirely, dilated, much larger than the side-lips, thus lengthening the side-lips. The lip is entire, but with an appendage consisting of two tubercles; anthers terminal, d-ciciduous, moveable like a lid, with two distinct cells; column elongated; germen on a twisted stem.

S. Lecotii has the leaves oblong-lanceolate; stem triangular; lip obovate, longer than the petals; flowers from 6 to 12, in a lax spike, yellowish in colour; the sepals lanceolate; petals linear; the hypantherium is large, ovate, inclosed in the whitish sheaths of the decayed leaves. It is the type of some authors. It is found in sappy bogs in Norfolk, Suffolk, and Cambridgeshire, but is very rare.

SUCCESSION DUTIES. For many years persons succeeding to personal property (including leaseholds), whether they took by will as executors or legatees, or merely as administrators or next of kin, were charged with Legacy Duties. The duty was assessed on the property, whether real or personal, according to the estimated gross value of the personal property of the deceased. The legacy duty was chargeable after the estate of the deceased had been settled, and the stamp duty was to be paid on the settled estate. The duty was paid by the successor, and the property was subject to the settlement duties, and the duty was charged on the property at the time of settlement. The duty was chargeable on the property at the time of settlement.

SUE, EUGENE, the popular romancist, was born at Paris Dec. 10, 1804. His ancestors, who came from Lapalme, near Cannes, in the south of France, settled in the French capital at the beginning of the 16th century, and having made a fortune by trade, left it to their posterity. A number of respectable physicians, two of whom becamecelebrated, and enjoyed a very extensive practice. Joseph Sue, his grandfather, and Jean-Joseph Sue, his father, are both mentioned with honourable distinction in the national biographies of France. The latter, who had been principal physician to the Hôtel de la Marine du Roi, and anatomical lecturer to the École Royale des Beaux Arts, during the reign of Louis XVI., was one of the household physicians to Napoleon I.; and his son, Eugene Sue, was the original of the poet at the font by the Empress Josephine and her son Eugene Beauharnais, from whom he derives his Christian name.

Dr. Sue, having but two children—a son and a daughter—was desirous of bringing up his son to his own profession, and the latter was proposed for his name and fortune, as well as at the schools of Paris; and, thanks to his father's position and influence, was enabled at the age of twenty to enter a company of the Royal Body Guards as aide-major.

He was soon after transferred to the staff of the French army preparing to ent-r Spain under the Duke of Angoulême. In this campaign he was present at the siege of Cadiz and at the Tucacadero in 1822. In 1825 he quitted the land for the sea service, visited America, Asia, and the coast of the Pacific, and the islands of the South Seas, which he has since described with indisputable power in his earlier tales. He was present in 1828 at the battle of Navarino, on board of the frigate Louise, and after his father died at the age of sixty-nine, leaving to his son an enormous estate of 40,000 francs (1600l.) a year, besides a splendid museum of anatomy, valued at several thousands more, bequeathed to the nation. Eugene Sue, at this time in his thirty-sixth year, and the first of his line who had ever been the head of a family, his family having acquired so much distinction, and to which he owed his fortune. His taste inclining to art, he became a painter, and in that vocation entered the studio of Gudin. At the same period he felt an ambition to signalise himself in literature, and this was gratified by the insertion of some slight articles in the journal recently established by Emile de Girardin—Le Voleur. Encouraged by this success, he began to write tales descriptive of sea adventures, publishing in 1830 his "Maman de Poivre" and "Salamanche." The two former were rejected by the trade, he therefore published them at his own risk. In 1832 he had already become popular both with publishers and their subscribers. But it would be quite a mistake to suppose that this success was due only to the talents of the author. A man at that time could repudiate it more; wherever he went he was loud in denouncing it. His father's name and his private fortune gave him access to the best company; he selected the highest for his cultivation, and lived among the old families of France.

Sue was one of the first to try his skill in framing those historical romances which the genius of Sir Walter Scott had rendered so universally popular. A new market had been opened for the purchase of historical novels, and Sue was quite a success. He could, as the saying is, supply the public with the first volume on account of the name, and refused to buy all the other volumes on account of the work. From 1833 to 1840, Eugene Sue had confined himself to the narrative; he had written nothing else. He was conscious of this, and he emulated, if not to rival, Fenimore Cooper in sea adventures, and Sir Walter Scott in historical delineations. But at this period the novels of Balzac in France, and those of Charles Dickens in England, had created a taste for the novel of real life, or as the French call it, le Roman de Mœurs. He therefore resolved to adopt the new style, and to this change we owe 'Arthur, the Hôtel Lambert,' and 'Mathilde,' published in 1841 and 1842. Making allowance for those licences in morality which are so frequently found in the current French fictions as well as dramas, there is a skill in the combination of the plot, and a power of description in the incidents, in 'Mathilde,' which his earlier tales did not prepare the reader for. The highest critical authorities have never been more voluminous in their praises. It is the highest and superior novel. It was in this work that Eugene Sue first started that idea of the moral Howard, going about scourging the poor, redressing wrongs, and obliterating the wicked, which he developed afterwards in the 'Mysteries of Paris,' and the 'Engineer's Dream' during the Republic. Of the latter, the whole of the four years from 1843 to 1846 was taken up with these baleful writings, and the ferment and agitation of the public fancy was excited to the highest degree, without repose or relaxation. The original terms of this novel each week were 1,000 francs (400l.) but it is understood that they were purposely extended and developed, on account of their unprecedented success, and much larger sums allowed for them to
The author. They were afterwards republished in volumes, going through many editions, and being translated into most living languages. "Martin, l'Enfant Trouvé," appeared in 1846 in the form of "Sloths," and "Les Deux Pêchés Capitaux," in the same paper in 1847-48. Perhaps the most serious censure passed on his writings was that passed on this last by the author himself when he said in a bravado, "that he would show the fair side of all these sins;" for "they contain the sentiments of the whole town, and in nothing else but an apology for each and all of them. The first of these tales—"Pride"—is perhaps the masterpiece of Eugène Sue; the second tale—"Envy"—contains one very dramatic scene; but his "Avarice," his "Sloth," &c., are unworthy of his reputation.

The Mystères du Peuple," published in 1858, is the last fiction of any note produced by the pen of this voluminous writer. It is intended as an exposure of all the misery and injustice to which the common people of every country have been reduced in all ages of the world. After the Revolution of Feb. 1848, Sue, who had abandoned his early conservative principles for extreme democratic and socialistic ones, was elected a representative of the Assemblée Nationale; but his election of Napoleon III. he took no part in politics. He died at the age of 62.

SURGERY. Some references which have been made in other parts of this work will here be made good. Anus Fistula. One of the most frequent diseases of this part of the body is that which is commonly known by the name of Fistula, or Fistula in Ano. This disease consists of a fistula or sinus by the side of the rectum. It sometimes opens externally, without communicating with the bowel, and is then termed an anal and external fistula. It more frequently communicates with the bowel, without opening externally, and is then called blind internal fistula. Usually, however, these sinuses have an opening internally and externally, and the disease then constitutes complete fistula. In this latter form pus, flatus, and faeces may be discharged from the openings. It is accompanied by heat of the parts, great discomfit, and sometimes pain and spasm of the sphincter muscles. It is sometimes attended with acute inflammatory catarrh of the ano and the greatest pain.

When this kind of ulcers occurs, the healing is prevented by three circumstances:—1. The fistulous condition of the cavity. 2. The presence of foreign matters. 3. The frequent motion of the part by the action of the neighboring muscles. This disease originates most frequently in the interior of the bowel by a small ulcer, which, extending, at last produces a second opening. It is often found in persons labouring under pulmonary consumption, and its persistence and inconvenience are increased by the constant cough which accompanies that disease.

The treatment of fistula is simple, and usually very successful. By laying open the whole of the sinuses and dividing the bowel, the pain subsides, and the patient obtains to the cure of this disease are removed. The mode of operating in this case is simple. A grooved probe is introduced into the external opening until it passes out at the internal opening. A probe-pointed bistoury is then introduced along the groove, and the sinus is ligatured throughout its whole length. Usually no important vessels are divided in this operation, so that all that is necessary after is to introduce a slight dressing of lint. An opiate should be given after the operation. A fistula or sinus will consist in an enlarged condition of the veins supplying the fistula, which are divided by the process, in two kinds, external and internal. It seldom occurs before puberty, and is more common in females than males, and in the rich and luxurious, than in the poor and humble.

The fluid which is derived from the vein, or whatever tends to become blood to the lower part of the rectum, and to retard the return of blood from that part, favours piles. Thus they occur in pregnant females, in persons troubled with habitual constipation, abdominal tumours, obstructions in the portal system of veins, and in those who lead sedentary lives or who feed too well.

External piles consist of the congeries of varicose or enlarged veins, which are surrounded by a condensed and enlarged connective tissue, and are covered partly by mucous membrane and partly by loose ragous integument. The parts are sometimes inflamed, at other times free from any capillary development. This condition of the veins is such that it becomes ulcerated. It is under these circumstances that the coats of one or more of the veins give way, and they bleed to a greater or less extent. When this does not take place they do not bleed. These two states are called respectively bloodless and bleeding piles.

The treatment of this form of piles may be either palliative or radical. The radical cure consists in removing the part either by the scissors or bistoury, and leaving them to heal in the ordinary way, or a ligature may be passed round the enlarged vessels, and the strangulated part of the bowels. When this operation is not thought desirable, much may be done to relieve the enlargement and pain of piles by a palliative treatment. Whatever will remove the loading of the vessels in the lower part of the bowels will relieve them.

Some piles may be divided into three kinds:—1. Varicose veins surrounded by enlarged connective tissue, and covered by mucous membrane, and bleeding or blind. 2. Tumours of the nature of sarcoma. 3. A congeries of blood-vessels resembling erectile tissue, and occurring in the subcutaneous and peri-membranous parts. It is called complete when the vessels are acted on. When the tumours are replaced, no great inconvenience occurs. If, however, the bleeding continues, the patient becomes pale, thin, and weak; noises in the ear, light-headedness, and palpitation of the heart come on, in fact the symptoms are those of a serious internal disease.

The treatment in this case may be either palliative or radical. Frequently the latter course should at once be resorted to. The internal tumours are seldom of a kind to allow of the depressor ligature; it is therefore the safest process. When the base of the tumour is small, it may be pulled down by a tenaculum and a single ligature placed round it; but when the base is broad, a needle with two ligatures is passed directly through the tumour, and ligatures are passed alternately in each until the base is reduced. The cautery is of very little value; the first application is very painful and difficult, and wherever circumstances will admit is greatly facilitated by the use of chloroform. After the operation opiates should be given.

Nitric acid has been recently recommended in these cases, but unless the tumours are small, and the cases slight, the remedy is liable to fail, and after the infliction of much pain the operation must be had recourse to. Should the palliative be had recourse to, all efforts should be made to enclose the head of external piles, must be attended to. Astringent remedies and opiates must be injected into the bowels. The bowels must be regulated, the liver looked to, and the lahmorrage is considerable, gallic and tannic acid, with acetate of lead, may be administered. Protopsins Anis is a very frequent and troublesome affection of the lower bowels. In consequence of relaxation the rectum passes down, and becoming exerted protrudes beyond the anus. This protrusion may be either partial or complete. When the whole part of the bowels comes down, and partial when the mucous coat alone descends. The latter is the most frequent, and sometimes accompanies internal piles. Children and old persons are more liable to the complete form. The quantity of mucus is increased from the former annular enlargement to a tumour as large as a child's fist. It is sometimes accompanied with inflammation, and the
mucous membrane throws off a coloured discharge. Great pain and uneasiness are often felt, and general languor and debility are present.

Acute Arteritis. The treatment is either palliative or radical. When this disease depends on general constitutional weakness, tonics, change of air, and a proper regimen, will restore the patient to health. The bowel should always be returned as speedily as possible, and the bowels should be kept open by the use of unctuous lubricating the parts. When they are softened, leeches should be applied and rest secured before attempting reduction.

The radical cure is effected by removing one or more of the redundant folds of the mucous membrane by the knife or ligature. If the disease is at the base, the removed parts, or the bowel may be left intact, and a portion of the redundant external integument may be removed, which by its subsequent contraction prevents the painful protrusion.

Imperforate Anus. Children are occasionally born without an anal orifice. Three forms of this malformation are described: 1. The rectum may be fully developed, and have its orifice closed by an external membrane, or a septum may be developed at some distance from the orifice. In the treatment of this form of imperfection, it is no longer required than an incision through the obscuring membrane. 2. The rectum terminates at some distance from the perineum, and there is a mere depression where the anal orifice ought to be. This is the most common form. It is more serious than the former. The membrane should be allowed to accumulate, and pressure being made on the abdomen, an incision must be made down to the bowel, and a passage thus established. 3. In this form the rectum is very small, and the anterior wall of the cavity last may be performed, and failing this, an attempt may be made to form what is called an artificial anus. This operation is performed not only for imperforate anus, but in cases where, from tumors, or the impaction of foreign matters, the fecal matter is condensed and becomes obstructed, the sigmoid flexure of the colon is the part which is preferred for this operation. It may be reached from before or behind. The former is the easiest operation; the latter is the most convenient position for the new opening to the patient. In performing the latter operation, an incision is made midway between the last false rib and the crest of the ilium. The colon is then secured, an incision made into it, and the edges of the bowel brought in contact with the external wound by means of ligatures. This operation, has been successfully performed at the age of one year, and with the result of the imbecility of the lower bowel. In children with imperfect anus, however, it seldom succeeds, as other malformations often exist which speedily terminate the life of the patient.

Acute Arteritis, is either limited to a particular spot, or it spreads along the course of the artery. When limited, this disease arises from external injury, and is a common result of wounds and ligatures. In the milder forms, this inflammation is attended with the exudation of a plastic matter, which fills up the artery and leads to its obliteration, a result which is sought for in the application of a ligature to arteries. The inflammation may, however, proceed to suppuration and ulceration, when the coats of the artery are opened and the blood escapes. In the latter operation, an incision is made midway between the last true rib and the crest of the ilium. The colon is then secured, an incision made into it, and the edges of the bowel brought in contact with the external wound by means of ligatures. This operation, has been successfully performed at the age of one year, and with the result of the imbecility of the lower bowel. In children with imperfect anus, however, it seldom succeeds, as other malformations often exist which speedily terminate the life of the patient.
tures with that of the abnormal vascular cells. Also in the neighbourhood of the trunk the blood-brain barrier is broken down, and the leucocytes can pass through it, and obviously carrying on a plentiful and active supply." (Miller, "Practice of Surgery.") Such is the nature of those tumours which partake of the character of true erectile tissue. Like the normal erectile tissue, also, these become enlarged and diminished in size, according to the singleness or activity of the blood circulating through them. They are compressible, elastic, and of a reddish hue. They are usually subcutaneous, but they are sometimes intramural. The most common symptoms are pain in the region of the head, neck, back, and buttocks. The tumour pulsates synchronously with the heart, and may be considerably diminished in size by pressure, but resumes its usual condition when the pressure is removed. On occasion the tumour is so soft and dull and rough, sometimes accompanied by a vibratory thrill.

Ureteral calculus is likely to occur in these tumours, and lead either to great haemorrhage or their cure.

Erectile tumour may be treated in three different ways:—

1. The tumour may be removed. This is always better done by the ligature than by the knife.

2. The tumour may be starved by diminishing the arterial supply. This is performed either by the application of a ligature to the artery or arteries which supply the tumour with blood.

3. The structure of the tumour may be changed. This may be effected in various ways: as by pressure, the introduction of a catheter, the application of a hot bladder, nitric acid, or other agent. A hot needle may be run through, or a wire connected with the poles of a galvanic battery may be passed through the tumour. All these plans have been found to succeed with small erectile tumours.

A tortuous and dilated condition of the arteries frequently occurs in the smaller arteries, and produces a painful tumour. It may be removed in the same manner as varicose veins.

Any operation applied to the opening of an artery for the purpose of drawing blood, as phlebectomy is applied to the same operation in a vein. When it is thought desirable to take blood in large quantity and with much rapidity, it is better taken from an artery than from a vein. This operation however is more difficult to perform, and may be attended with ulterior consequences. Hence phlebotomy or venesection is always preferred, except under urgent circumstances, as the means of drawing blood from the system. When arteriotomy is performed for the sake of blood-loss, the operation is rendered imperative by the nature of the temporal artery, which is generally selected. In this position the wound is easily healed afterwards by pressure. The accidental wounding of an artery, as is sometimes the case in battle, causes in the arm, may lead to false aneurism and the necessity of placing a ligature round the wounded artery. Sometimes false aneurism follows arteriotomy in the temporal artery, and in this case it becomes necessary to ligature the arteries on each side of the wound. Sometimes on removing the compress after arteriotomy, an ulcer is found to be formed. If the ulceration spreads, the vessel may be opened and haemorrhage occur. In this case also the artery must be tied.

BLADDER, DISEASES OF. This bladder, like every other organ of the body, is liable to inflammation. This disease is called Cystitis. When present there is pain and tenderness in the region of the bladder, also in the region of the perineum and <insert>...> the urethra. The urine is voided very frequently. The bladder may be distended above the pubes, there is dulness on percussion there, and pressure produces great pain. Sickness is frequently present, the pulse becomes rapid, the skin hot, and at last symptoms of the absorption of the urine present themselves, and unless relieved, the cases become fatal. In the other case, tonics and other remedies necessary for the debilitated state of the system must be employed. Generally, however, little can be done, and cleanliness and the use of urinals are the only means left.

Retention of Urine. This arises from various causes, and the treatment must vary accordingly. The symptoms in all cases are, an inability to evacuate the urine, whilst the desire to do so is constant and frequently accompanied with pain. When the desire is experienced and urine relieved, the bladder becomes poisoned by the urine. All these symptoms are removed by the removal of the urine. This may frequently be done by the catheter, but the disease can only be permanently cured by the removal of the cause.

The following are some cures and measures of this disease.

of these cases a special treatment is necessary, but in all it should be remembered that fatal results will occur unless the diseased viscus is emptied of its contents. It often happens that for this purpose the catheter cannot be passed into the urethra; under these circumstances the only means left is to puncture the bladder. This operation may be performed from the perineum, the rectum, and the pubes. In puncturing the bladder from the perineum an operation is performed that is perfectly innocuous, and without risk. When this operation is deemed advisable, the bladder may be reached from the rectum and punctured here. It is only when these two methods are found to be impracticable, that the operation on the perineum, the abdomen in the region of the pubes has recourse to. These operations are not often performed: "but any one of them is much preferable at any time to postponement of relief, and consequent disaster by extravasation; and all, too, are preferable to passing a cat-tail catheter, by sheer force through an impassably strictured urethra." (Miller.)

Diseases of the Prostate. The prostate gland is liable to the various diseases of other parts of the urinary organ. It may be inflamed, or abscess may occur in it, or it may be subject to malignant disease. It is, however, most liable to enlargement or hypertrophy, which is one of the most troublesome and frequent diseases to which old age is liable. The causes of this hypertrophy are, first, local, due to result of inflammatory action, and the other is an enlargement independent of that process. The first is only temporary, and may be frequently speedily removed by treatment. It is the result of structure, gleet, affection of the rectum, as in the distended bladder, and of the pugilistic, the recumbent position, and counter-curritants, are the proper treatment. The second form of enlarged prostate is more difficult to manage. It is one of the consequences of increasing age. The enlargement in these cases may be partial or general. One of the most painful consequences of either is a difficulty in passing the water. This comes on gradually, and is also attended with difficulty in emptying the rectum, as this organ is pressed on by the distended prostate. In the early portion of the disease, empty the bladder more frequent, and the act is less perfectly accomplished, and a portion of residual urine remains in the bladder behind the enlargement. Under these circumstances the bladder becomes irritable, and chronic cystitis is established. The symptoms of this disease are then added to those of the enlarged prostate.

There is no cure for this state of things, and the treatment is consequently palliative. Much, however, may be done for the comfort of the patient. All excess and imprudence in diet must be avoided. Milk, eggs, and fish, which are rich in blood, must be maintained as much as possible. The bowels regulated by onuncata and gentle aperients. Opium, iron, mineral acids, and tincture, may be given according to circumstances. In order to prevent distension the catheter may have recourse to, and the water drawn off occasionally.

Breast, Diseases of. The mammary gland, especially in the female, is liable to various diseases, requiring the attention of the medical man.

Irritabla Mamma. In both married and unmarried females the breast is liable to irritation from sympathy with other parts of the system. In these cases there is often great pain and uneasiness in the breast, and the whole system suffers more or less. The breast was swollen and red in the external elevation of the mamma. The pain is sometimes intermittent or periodic, similar to neuralgia. When the general health is affected this must be attended to. Opium and belladonna may be employed internally, and nitrate of silver, bismuth, and aconite, have been recommended externally.

Mammitis. Inflammation, acute and chronic, of the substance of the mamma is not an unusual disease. It causes great suffering, and is common during the period of lactation. The pain is intense; the breasts are swollen, and tender to the touch. From the first there is a tendency to suppuration. The secretion of milk is perverted and arrested. In the treatment leeches and warm fomentations are used. When the body is wet, the bowels should be kept open, and the fever subdued. When matter forms it should be early evacuated. A chronic inflammation is sometimes observed. When this is the case stimulant applications to the breast will be found useful. Where this is attended with abscess it should be opened, so as to give free exit to the pus, and pressure applied. 

Tumours of the Breast. The breast is subject to various kinds of partial and general enlargement. The "chronic mammary tumour" of Sir Astley Cooper consists of a partial hypertrophy of the gland. Enlargement of the whole gland also frequently takes place. These enlargements may be got rid of by pressure and treatment of the general health. The tumours may be of the nature of cysts, abscess, hydatids, and malignant tumours. In many of these cases it may be necessary to remove the breast. This is done in the following manner: "The patient having been placed recumbent, and duly anesthetised, the arm on the affected side is raised and held by an assistant, as to stretch the pectoralis major and facilitate incision. The knife is entered in the axillary aspect of the tumour in a line with the mamillo, and is moved in a semi-elliptical direction towards the opposite point; a similar proceeding is adopted—above or below, as the case may be—to complete the ellipse, and the size of this space necessarily varies according to the extent to which the integument seems to be involved, and according to the natural latticiness of the parts. It is a fault to take away an undue amount of sound tissue, for it interferes with the effect of the incision in effecting and maintaining apposition of the wound; but it is a worse error to leave tailed parts, whereby reproduction of the disease cannot fail speedily to ensue. It is well to make the lower incision first, otherwise its course and position are apt to be uncertain. In case of a second tumour it is best that, after the knife is sloped through the subcutaneous part; and regular dissection is proceeded with from the axilla downwards, dividing the principal vessels and nerves at once, and so rendering the subsequent steps of the operation comparatively bloodless and free from excess. The absence of the organ, with its hinder of comparatively sound tissue, in the case of malignant tumor, having been removed, is carefully examined on every aspect by both sight and touch; and, if need be, a portion of the organ, to the extent of the removal. If the perforation is to be feared, the wound is brought together and treated in the ordinary way."

Much has been written of the removal of malignant tumours, especially of the breast, by means of excisions. It is always difficult to decide exactly as to whether a tumour is malignant; and from all that has hitherto been made known of these formations, it would appear that, if they are cured by general or local treatment, the inference is that they are malignant. Without the aid of histology, or the evidence is very decisive that we possess no internal remedy that has any known influence over the progress of those tumours which are truly malignant. A recent American writer has expressed a decided opinion that the presence of the disease should be confirmed, by removal as a general and local treatment, which has been undertaken with success, and reported on in this country. The cases referred to were treated at the Middlesex Hospital. The general treatment consisted in the administration of iodide of arsenic and the Sanguinaria Canadensis. The local treatment consisted in the application of the Sanguinaria and chloride of zinc. The method employed was to make a decoction of the Sanguinaria, and, with an equal quantity of the chloride of zinc, to make the whole into a paste with common flour. This was then applied to the incisions, and the wound surrounded with zinc paste, which was continued from two to three weeks, till the whole depth of the tumour was penetrated and removed. When this was effected the application of the paste was discontinued, and the wound allowed to get well. The Sanguinaria seems to exert no effect in this condition of the disease. With the chloride of zinc however, the following passage concludes the report of the surgical staff of the Middlesex Hospital on this mode of treating malignant tumours: — "The last peculiarity of this treatment is the practice of incisions; but I may say in opinion that this is its only but its very great merit. The Sanguinaria is inert; the chloride of zinc paste was known before; but the incisions constitute a new feature in the treatment of cancerous tumours for which we find no parallel in the writings of the past, or in
the practice of present surgeons. Cancer in its constitutional nature remains as ruthless and as unassailable as ever.

SUSZMAMITE. [Mineralogy, S. 1.]

SWEDEN. In 1839, to which date the population was given in the previous article, it amounted to 3,109,772. The following table shows the increase, and also the läns or provinces into which Sweden is divided—

This area, increased by 3848 square miles of water not included in the läns, and the population column by 97,567, the number of the inhabitants of Stockholm, the capital of the kingdom, gives the total läns 195,351 square miles, and the total population 3,641,600.

Manufactures.—The industrial products of Sweden comprise vast quantities of linen, which is manufactured in most every house, woollen-cloth and other stuffs, refined sugar, tobacco, paper, leather, glass, some callicoes and other cotton goods, cotton twist, silks, china-ware, cast-iron, sailcloth, soap, spirits, beer, &c. Ship-building is carried on to some extent in most of the harbours of the Baltic.

Internal Commerce.—The internal commerce consists of corn, salt, and manufactured goods, especially the linens of Wenerborg’s Län, which are carried to the most remote parts of the country, is very considerable. This commerce is facilitated by the excellent roads, and in winter by the whole country being covered with snow for four or five months, which renders the conveyance of goods in sledges easy and expeditious. In summer a like advantage is derived from the navigation of the sea, which washes most of the provinces. The Trollecten Canal is navigated by a great number of barges, which bring down to Göteborg, for export, large quantities of iron and steel, and timber in planks and boards; and they carry into the interior corn, whisky, salt, herrings, sugar, butter, fish, wine, and some other articles. Large barges ply also on the other canals, conveying heavy goods of different descriptions, such as bar-iron, alum, corn, salt, herrings, and strömings, whisky, bricks, and tiles. A railway has been commenced, of which a portion, from Orebro to Arboga, with a branch from Dylla to Nora, was opened in 1858. It is intended ultimately to connect the Werner lake with the Malma lake, and thence with Stockholm, Arboga being a great entrepôt for iron.

Navigation and Foreign Commerce.—The Swedes are much given to sea-faring life. Their vessels visit most of the countries contiguous to the Baltic, and they are also employed in the carrying-trade between other countries, especially in the Mediterranean and on the coasts of South America. The mercantile navy at the end of 1855 numbered 2874 vessels (carrying together 126,326 lasts), exclusive of those carrying less than ten lasts; and 131 steamers. The total number of foreign (including Norwegian) ships that entered Swedish ports in 1855 amounted to 6733, carrying 290,880 lasts; the departures numbered 10,665 vessels, measuring 428,384 lasts. The imports were valued at

56,661,000 crowns; the exports at 58,598,000 crowns. The foreign trade extends to most countries in Europe and America. The chief imports are brought from the following countries, which are named in order of the values:—The Hane Towns, Great Britain, Brazil, Norway, Russia, Denmark, United States, East Indies and Australia, Prussia, and the West Indies. The best customers for Swedish exports are Great Britain, Denmark, the France, Prussia, United States, Russia, and Portugal.

The principal articles of export from Sweden are iron and timber. Norway takes a considerable quantity of iron, and sends in return. Stockholm receives from Finland the fourths of the fire-wood which it consumes, the northern provinces not being able to supply the article either so cheap or so good. Finland also exports to Stockholm meat, butter, cheese, bacon, flour, hides, pitch, and tar. Other articles of exports are copper, charcoal, tar, pitch, hemp, oil, paper, tree-bark, tobacco and snuff, bricks, furs, some linens, vessels, and some minor articles. The chief articles of import are: sugar, coffee, salt-fish, hides, cotton-twist, cotton in wool, woolen stuffs, linens, cottons, wines and brandy, wool, dye-stuffs, rahtas, almonds, pepper, cinnamon, arrack and rum, butter, bacon, tobacco, soap, tar, oil, ginger, lacquered ware, tea, tallow, potashes, and oil.

Education.—Sweden has two universities, Uppsala and Lund. The average number for the last two years was about 1000 students; at the latter, between 400 and 600. There are besides, 12 gymnasia for higher instruction, preparatory to the universities; 41 lardems skola, or grammar schools, and 40 apolo- logist schools, where the common branches are taught, with, in some cases, French and English. For primary education, the law of 1849 commanded the erection of a school in each commune or parish. Owing to the sparseness of the population this was found to be in many instances impracticable; in such cases however the communes are divided into districts, each of which is visited in turn by teachers or schoolmasters. Schoolmasters are trained by government and paid by the communes in kind. In 1860 there were 9107 stationery and 1351 amblatory schoolmasters. Of the masters, 218 were clergymen and 690 church clerks. In that year, 143,927 were employed in national and 112,900 in parochial schools, 156,175 in amblatory schools, 129,996 were instructed at home, 6233 in the secondary schools above named, and 17,468 in private schools, making a total of 432,388 altogether under instruction. It is a general practice in Sweden for parents, especially those who live in the country, to instruct their children in the long winter evenings.

Finance, &c.—The income of the state has been calculated for 1855 and 1857 at 14,566,300 crowns; and the expenditure for 1857 at 14,567,800 crowns; but in the budget proposed for 1858, 1859, and 1860, the receipts are set down at 24,527,800 crowns, and the expenditure at 24,517,800 crowns. These sums are for Sweden independent of Norway. The strength of the army and navy are stated under Military and Naval Forces. The present king, Oscar I, succeeded his father in March, 1844.

to construct free from that impediment. And, even whilst she was upon the stocks, she was considered to present such excellent qualities, that it was deemed Captain Symonds had already given sufficient proof of his skill in naval architecture to be entitled to the highest post and respectability that profession. In 1833 on the 9th of June, he was offered, and accepted, the office of Surveyor of the Navy, in succession to Sir Robert Seppings. This appointment was associated with the entire removal of restriction as to the amount of tonnage in the navy, and to the rights of the navy there had liberty for the exercise of judgment and talent in designing ships, which had not been granted to the commissioners or surveyors of the navy before: so that he might at once build ships of the highest conditions of excellence that both science and practice had yet indicated. This freedom from conditions in determining the dimensions of ships, was taken ample advantage of by him; having a great principle to bring out in practice, he applied it with a decision, which, in a short time, altered the general character and indispensable part of our navy. He had the merit of having boldly taken the lead in a path which future constructors, intending to carry on improvements in our ships, may pursue with the highest advantage. Considerable difference of opinion exists as to the value of the totality of qualities possessed by Captain Symonds’s ships; but it was remarked in 1849, two years after he had retired from office, that of the 180 vessels of different kinds, built during the period of sixteen years, for which he was surveyor of the navy, and all upon the same principles, he had been superior in construction, in form, than any shipman, as was originally adopted in the Pantalone, none had foundered.

Captain Symonds received the honour of knighthood in 1836. He had received the thanks of the Admiralty in 1830 for a memoir containing sailing Directions for the Adriatic Sea; and again in 1837, for “the valuable qualities of his several ships, and for improvements introduced by him into the navy;” he was elected a Fellow of the Royal Society on June 4th, 1838, and nominated a C.B. of the Civil division in 1848. In 1849 he was a Naval Commissioner on the retired list. He died, March 30, 1856, on his voyage from Malta to Marseille.

(O’Byrne, Naval Biographical Dictionary; Fincham, History of Naval Architecture, &c.)

SYNAPTE. [Class. Amebida, S. T.]

SYNAPTE, a family of Echinodermata, belonging to the order Holothuriidae. It is characterised in this order by the absence of suckers. It is represented in the British seas by the genus Chirobatia, which has a cylindrical and vermiform body, elongated tentacles, digitate at their extremities.

C. digitata has a vermiform body, white with orange spots, the tentacles long, punctuated, digitate. This animal was first found by Montagu on the shores of South Devon. It is a very rare and curious specimen in British Star-Fishes, says a writer on the subject, having never been seen a living specimen.

SYNAPTIDE. [Class. Amebida, S. T.]

SYNATHIDAE, a family of Fishes, embracing, according to some authors, the Pipe-Fishes, the Sea-Horses, and the Winged Sea-Horses. These forms are sometimes assigned to distinct families, as in the following definitions:

Syngnathidae, Pipe-Fishes. — Body prolonged, slender, linear, or angulated; mouth greatly prolonged, cylindrical, mouth terminal, vertical. Ventral fins absent; caudal fin wanting in some.

Hippocampus, Sea-Horses. — Head and body compressed; snout narrow, tubular; mouth terminal. Pectorals small; dorsal single; anal two or three.

Pogonias, Winged Sea-Horses. — Body broad, depressed; snout suddenly contracted, narrow, somewhat protractile; mouth terminal, beneath. Pectorals generally large; caudal fin small.

They all agree in having the endo-skeleton partially ossified; exo skeleton ganoid; gills tufted (hence the group is named Lophobothria), in the opercular aperture being small, and the swimming-bladder without an air-duct. We shall illustrate this family by a short description of the British species:

Syngnathus has the body elongated, slender, covered with a series of indurated plates arranged in parallel lines. Head long; both jaws produced, united, tubular. No ventral fins.

In certain of the species the males are furnished with an elongated pouch under the tail; these are called
TAL

TAHITI. [OTAHITI.]

Talfourd, Sir Thomas Noon, Knt., was born January 26, 1796, at Dockey, a suburb of the town of Stafford, where his mother was then on a visit. His birth was premature. His father was a brewer at Reading in Berkshire. His mother was a daughter of Thomas Noon, minister of a congregation of Independents in that town, to which seat his father also belonged. Thomas Noon Talfourd was educated at the grammar-school of Reading, under Dr. Valpy, for whom he always entertained an affectionate respect. In the year 1813 he was placed for legal instruction under Mr. Citty, the special pleader, and in 1818, was called to the bar. He collected a personal fortune by a year's escape from the egg the tail is covered with a fin-like membrane, and it also possesses pecoral fins. During their growth the caudal membrane and tail fins are not absorbed.

Hippocampus—The jaws are united and tubular, the mouth placed at the end. The body compressed, short, and deep. The whole length of the body and tail divided by longitudinal and transverse ridges, with tubular points at the angle of insertion; both sexes have pectoral and dorsal fins; the females only have an anal fin; neither has ventral or caudal fins.

H. breviceps, the Sea-Horse, or Short-Nosed Hippocampus, is occasionally met with on the British coasts. The habits of these creatures are very singular. When swimming about they maintain a vertical position, but the tail is ready to grasp whatever meets it in the water. It quickly entwines in any direction round weeds or other objects, and the angle of intersection: both sexes have pectoral and dorsal fins; at their prey with great dexterity. When two are together they often twist their tails together. Their eyes move independently of each other, as in the chameleon.

Pegasus has a smut as in the previous genera, but the month is under it, and movable. Two distinct ventral fins behind the pectoral, which are often large, hence the name of Pegasus, or Flying Horse. The species are found in Indian Seas.

(Tarrett, History of British Fishes; Adams, Manual of Natural History.)

SYNODUS. [SOPHOPA.]

SYRINGINE. [CHEMISTRY, S. 2.]

SYRINX. [SYRINCOIDEA, S. 2.]

SYSTEM, SEXUAL. [SEXUAL SYSTEM, S. 2.]

Mr. Serjeant Talfourd may be said to have added two valuable encomiums to the statutes of the realm—the Custody of Infants Act (2 & 3 Viet., c. 54), and the Copyright Act, which he first introduced in 1837, but which was strongly opposed, and was not passed into a law till 1842 (3 Viet., c. 45), when he was not a member of Parliament, and then in a modified form.

During all this period of legal and parliamentary activity Mr. Talfourd continued his labours in literature. He was for several years law-reporter of circuit cases for the 'Times' newspaper, and he continued to contribute to the 'New Monthly Magazine,' and also to the 'Retrospective Review,' and the 'London Magazine,' when he was called to the bar by the authorities of the Middle Temple, February 9, 1821, and in 1822 he married the daughter of John Towell Rut, Esq., of Clapton, near London, the editor of Dr. Priestley's works. He soon afterwards joined the Oxford Circuit. By steady application, rather than by any peculiar aptitude or liking for the law, he gradually rose in his profession. He was a fluent speaker, distinguished by feeling and fancy, more than by argumentative powers. After about ten years practice he applied for a silk gown, but his claim to the dignity at the bar was not entertained by the house of Commons, he therefore, in Hilary Term, 1833, assumed the gown, and became Mr. Serjeant Talfourd. He was also for some years Recorder of Banbury.

At the general election in 1835 Mr. Serjeant Talfourd was returned to parliament as one of the members for the borough of Reading, Mr. Fyafe Palmer, the previous liberal member, having retired. In 1837 Mr. Palmer again came forward, and was returned with Mr. Talfourd. At the next election two conservatives were returned, and Mr. Talfourd was out of parliament from 1841 to 1847, when he was again returned for Reading, and retained his seat till July 1849, when he vacated it on his being appointed successor to Mr. Justice Colman in the Court of Common Pleas, on which occasion he also received the honour of knighthood. As a member of the legislature
depth of emotion, and truthfulness of thought and expression. They may be rather regarded as dramas of poetic sentiment and description. The blank verse is smooth, graceful, and "in linked sweetness long drawn out," but all the grandeur of its language and the wealth of its forms are obscured by the redundancy of the diction.

In 1837 Mr. Tarlton published the "Letters of Charles Lamb" and "Sketches of a Country-house in Staffordshire," which was followed, in 1843, by "Anecdotes of the Life of S. 1844, after the death of Lamb's sister, he published "Final Memorials of Charles Lamb," consisting of Letters, 4to, 2 vols. 8vo, a domestic tragedy of the most affecting interest, which had been long known to a few friends, but was not till then discovered to the public. On the 20th of June, 1844, he was created a Doctor of Civil Law by the University of Oxford. In 1845 he published "Lectures of Three Continental Tours in the Festivals of 1841, 1842, and 1843," 2 vols. 8vo, and in 1854, a "Supplement to the Vacation Rambles, consisting of Recollections of a Tour through France to Italy, and Homeward by Switzerland, in the Vacation of 1846," 4to, 8vo.

The journeys were all rapidly made, and the information which the volumes contain is very scanty. Some of his speeches as an advocate and also as a member of parliament were published in a separate form. He was an eloquent speaker, and had extraordinary command of language, but his style was too florid and studied. The translation is that of a sound lawyer for dicing cases, at the same time that his persevering labour, great practice, and love of justice, made him respected both as an advocate and a judge. In his private character he was amiable and social in an eminent degree, and he had a large circle of friends, chiefly literary and legal.

The death of Mr. Justice Tarlton occurred on the 15th of March, 1846. He had opened the assizes at Stafford on Saturday the 11th, and, by an early morning, while delivering his charge to the grand jury, and commenting on the increase of crime and its causes, he was observed to be much excited. Suddenly his face became flushed, his head bent forward, and his body swayed on one side. The most immediate symptom was thrown into the judge's chambers, where it was found that he had ceased to live. He was buried in the cemetery at Norwood, near London. He left issue three sons and two daughters. In 1856 the members of the Oxford Circuit placed a bust of him, sculptured by Longh, in the Crown Court at Stafford. It is an excellent likeness.

TALLOW, for TALLAGH. [WATERFORD.] TANACETINE. [CHEMISTRY, S. 2.] TAYLOR, J., &c. [ANATOMY.] TAPE-WORMS. [ENTOZOON; PHYSIC, PRACTICE OF (Worms). S. 2.] TAPITELÉ. [ARABE, etc., S. 2.] TARNAX-BULLE. [CHEMISTRY, S. 2.] TARDANUS. [BENZYL.] [DEER.] TARRAGON. [ARTEMISIA.] TARTARIC ACID. [CHEMISTRY, S. 2.] TARVÉE, JOHN CHARLES, was born of English parents at Dieppe, March 27th, 1790. At the breaking out of the war in 1793, his family, in common with all other English residents at Dieppe, were thrown into prison. At that time the little boy was staying at the country-house of a friend of his mother (M. F. Tarvit, de la Comarque, in the Cape de los Pinos et de Tarragona ou du Département de la Seine Infrérieure), and when his family, through the interest of friends, had the means of escape given them, he was left behind in France until an opportunity should offer to send him to England. This never occurred. But M. F. Tarvit, faithful to his trust, brought the child up as his own son, educated him partly himself and partly at the government school at Pont-Andemer, and at the age of fifteen took him into his own employment in the leather manufacture under the government. In the year 1808 M. F. Tarvit got the youth an appointment in the Administration de la Marine, in which service he remained, first as secretary to the admiral of the fleet at Toulon, then as secretary to the admiral at Brest, afterwards at Genoa, and Brest, till at the cessation of the war in 1814 he was enabled to renew his intercourse with his family. In March 1815 he obtained a short leave of absence, and hastened to England, where he found his mother, brother, and sister living. He returned to Paris at the expiration of his leave in April, where he found that Bonaparte had escaped from Elba, and had put himself at the head of his army, and that the king, Louis XVIII., had fled. Such being the uncertain state of affairs, and his own desire to return to England, he left his situation, and in less than a week rejoined his mother. He soon sought and obtained employment as a French master; first at the grammar-school at Maastricht in Austria, where he was sent at the age of 16, and then at the school to live at Windsor, and in 1829 he was appointed French master to Eton school, where he remained, and which situation he held till his death, April 10th, 1851, aged sixty-one.

Besides having written several elementary works, now used at Eton and other public schools, he published, while at Maastricht a Dictionary of French and English. Verbs, showing their Government and Peculiarities. During his residence at Windsor he wrote his translation of the "Inferno" of Dante in French verse, with a volume of notes; and subsequently Lectures on French History, Paris, Ancient and Modern, and some minor works. He also revised the grammars of Uanostrochter and Lizerio, and Nugent's Pocket French and English Dictionary. For the last ten years of his life he was engaged on his "Phrasological French and English Dictionary," an original work of immense labour, and which has given to its author a high place amongst those who have most distinguished themselves in philological pursuits.

TASMANIA. A full description of this colony, formerly more generally known as Van Diemen's Land, will be found in vol. xxiv. The following gives the material alterations that have taken place.

The population of Tasmania in 1847 had increased to 70,164, of whom 47,828 were males and 22,336 females. Of this total 33,173 were either free emigrants, or were born in the colony; the rest were then or had been convicts. Emigration to Victoria colony has combined with other causes to produce very material alterations in the population of Tasmania. On Dec. 31, 1865, it was only 69,962, of whom 7740 were convicts, although 10,887 emigrants had arrived during the year. The greater part merely made it the place of transit, but many of the old settlers must also have left.

Notwithstanding this drawback the colony is highly prosperous, and its trade and commerce have been continually expanding. The efforts of the local government are rapidly extending improvements on the island. Among the greatest works is a bridge over the Derwent, on the high road from Hobart Town to Launceston; it is of wood, and has 20 bays, or arches, of 32 feet span each.

The exports to Great Britain in 1853 included 6,514,751lbs. of wool (the average quantity for four years, 1849-52, had been upwards of 5,000,000lbs.); 9099 hides (the average number for the previous four years had been about 3000); 778 cwt. of tallow, 9,500 cwt. of spermaceti, and 405 tons spermaceti oil. The declared value of the imports of British produce and manufactures from Great Britain in 1853 was 1,405,927l., the average for the preceding four years being only about 420,000l. Of foreign and colonial produce, chiefly spirits, wines, and tobacco, imported from Great Britain, the declared value for 1853 was 694,790l. The number of sailing vessels entered as belonging to Van Diemen's Land on December 31st, 1864, was, Hobart Town, 1,473; Launceston, 479. Of Steam-vessels, 6, of 510 tons aggregate burden, were entered at Hobart Town, and 2 of 356 tons at Launceston. In 1854 the value of the imports was 2,604,680l., of which 1,776,694l. was from Great Britain; the exports amounted to 1,43,051l., consisting chiefly of wool, oil, timber, cattle, flour, and grain. The extent of land under cultivation was 127,732 acres, of which 49,920 were of wheat, and 33,320 of oats; while the sheep numbered 1,631,308, the horses 37,974, the horned cattle 17,900, and the swine 22,998. The land revenue had amounted to 112,226l.

Hobart Town, the capital of the colony, is built upon an undulating surface, on the left bank of the river Derwent. The streets are of good width, and laid out on a regular plan, and intersected with good bridges. Some improvements have been made of late years, particularly in the construction of a new market-place in the town, and of docks and wharves at the river-side. Several of the public buildings are handsome. A small rivulet which runs through the town, affords a supply of fresh-water.
population on December 31st, 1847, was 21,467, of whom 35 wereaborigines.

Locarno, the second town of the colony, is situated at the confluence of the North Esk and South Esk, which there form the Tamar, 40 miles from its outfall in Bass's Strait. It is 125 miles N. by W. from Hobart Town. Launceston contains a government house, an court house, jail, barracks, and other public buildings, and several places of worship.

Convenient wharves have been constructed. The population in 1847 was 10,100. The shipping trade is important. A good highway extends from Hobart Town to Launceston; there are inns along it at short distances from each other.

Richmond is situated on the Coal River, about 12 miles N.E. from Hobart Town, and contains a population of 8300. Longford has a population of 6000. Arcoxia is a small town in the county of Launceston, with a population of 838.

Tasmania is divided into 19 police districts, and each of the districts generally contains a town or village of the same name. Lincoln, Perth, and George Town at Port Dalrymple, are places of some importance. They are seated on the Tamar, or the Macquarie, as it is called, in the upper part of its course.

Government. — Tasmania is administered, under the 13 & 14 Vict., cap. 59, by a Lieutenant-Governor, who is appointed by the Governor of the Governor-General of New South Wales, of whom two-thirds are elected and one-third nominated. The judicature consists of a supreme court, courts of quarter sessions, and courts of requests.

A bishop of Tasmania was appointed in 1842, whose duties are divided among a clergy and dependents, and is divided into the archdeaconry of Hobart Town, containing 34 places of worship, and the rural deanery of Longford, containing 19 places of worship. There are also 13 places of worship in the Church of Scotland, 14 Congregational, 21 for Wesleyan Methodists, 15 for Independents, 3 for Baptists, and 2 for Jews. Of these bodies all except the Independents and Jews receive government aid.

There are numerous private schools in Hobart Town and Launceston, which are supported by subscription.

TAYLOR, GENERAL ZACHARY, late President of the United States of North America, was born Sept. 24, 1784, in Orange County, Virginia. He was the third son of Col. Richard Taylor, who had distinguished himself in the war of the Revolution, and who in 1789 removed with his family to Kentucky, where the settlers were then very few. Col. Taylor obtained from President Jefferson, May 3, 1806, a commission for his son Zachary as first-lieutenant in the United States Army. In 1810 Zachary Taylor married. On the breaking out of the war in 1812, having then become Captain Taylor, he was placed in command of Fort Harrison, a stockade on the river Wabash, for his defence of which against the attacks of the British he was subsequently rewarded with a knighthood.

He distinguished himself on several other occasions during the war, but when it terminated he was reduced from his brevet rank of major to his previous rank of captain, a step backward which he refused to consent to, and resigned his commission. He was, however, in the course of the year reinstated in his rank of major by President Madison. In 1816 he was placed in command of the post at Green Bay, on Lake Michigan, and on the 20th of April, 1819, received his commission as lieutenant-colonel. In 1832 he received his commission as colonel from President Jackson, and in that year served under General Scott in the Black Hawk war.

He subsequently held the command of Fort Crawford at Prairie du Chien, where he remained till 1836, when the Seminole war in Florida called for his services. The manner in which he there performed his harassing duties acquired for him great reputation among his countrymen, and the battle of Okeechobee, fought Dec. 29, 1837, gained him the rank of brevet major by brevet. In 1838 he was appointed to the command of all the troops in Florida, where he remained till 1840, when he commanded the south-western division of the army was assigned to him.

In 1844, on the annexation of Texas, General Taylor was ordered to Florida as a suitable measure for defending that country against a threatened invasion from Mexico, and in August he concentrated his troops at Corpus Christi. There he remained till March 11, 1845, when he broke up his camp and moved westward with a small army of occupation of about 4000 regular troops. He reached the Rio Colorado on the 20th of March, crossed it without opposition, and on the 29th of March arrived at the Rio Grande and encamped near Resaca de la Palma. On the 21st, 22nd, and 23rd of September, he attacked and captured the city of Monterrey, which was strongly fortified, and defended by a superior force. In February he gained the victory of Buena Vista, in which the Mexican army of 20,000 men under General Santa Anna, was defeated with very great loss by the American army of about 6000 men.

This victory led to negotiations for peace, and the treaty of Guadalupe-Hidalgo was signed on the 2th of February, 1848. In May, 1849, he returned to his residence at Benton Ronge, in Louisiana, where he had purchased an estate, and on the 1st of June, 1845, the Whig Convention in Philadelphia put him in nomination for the presidency. On the 23rd of June, 1850, Mr. Taylor was elected President of the United States of America, and on the 4th of March, 1849, he was inaugurated, and entered upon his term of office. He died July 9, 1850, at Washington, and was forthwith succeeded as President by Millard Fillmore, the Vice-President. He left a widow, one son, and two daughters.

TCHAD, LAKE. [AFRICA, S. E.]

TCHADDA. [QUOBA; AFRICA, S. E.]

TETHIN. [DEPOSITION.]

The name Tethin, or Tethin, is universally acknowledged by the Swedes as the greatest poet of Sweden, was born on the 13th of November, 1782, at Kykerud in Wermland. His father, also named Esaias, the son of a peasant, Lars Essalon, of Tegnaby, in the diocese of Vaxo, had a turn of genius. He became a student in the University of Uppsala. He took orders, and was the first of the family to assume the dignity of a surname. He took that of Tegnér, from his birthplace of Tegnaby, a village which is part of the township. On the Schoo of the University of Uppsala, as an appointed pastor, and which it may be noticed in is a remarkably ugly part of the country. It is in particular destitute of trees. "King Olof, the tree-farer, a man well known in Swedish history, took his pleasure there; his sons were all good men. The trees have not grown again for a thousand years." In February, 1792, when Esaias was in his tenth year, his father died, leaving a widow and six children, four sons and two daughters, in whose education he was a procusus. The four sons were all remarkable in their way. Lars Gustaf, the eldest, was of a mild and earnest character, strongly tinged with mysticism; Elof, the second, was full of wit and sentiment; the third, Johannes, was very apt in languages, and was married; and it is said that when he was desired to attend to what was going on in church, he could on his return repeat every word he had heard in it, without being able to draw any distinction between the lessons, the banns of marriage, and the sermon. Esaias, the youngest, was of a remarkable flexible character, and at different times of his life exhibited a striking resemblance to each of his brothers in their prominent characteristics.

At the time of his father's death, the two elder brothers, who were intended for the church, were already students at Lund; the expenses of their education quite absorved the resources of the family when deprived of a head, and the widow was grateful to a friend of her husband, Jakob Transtam, a Kronovich, or some other tax-collector, from taking the youngest off her hands, and make use of him to assist him in his business. Esaias soon made himself a most useful assistant, and was to the end of his life remarkable for his quickness with figures. He found among the numerous Scandinavian sagas of the 17th century, containing a number of Icelands sagas, with, in the same page, the Swedish translation: and almost his first attempt at composition seems to have been in a poem on the Saga of Njord, in the which he ascribes his name. The poem of "Fritiof," the great achievement of his early years, was founded on another. His only recorded attempt at poetry previous to 'Atle' seems to have been when a child at Millevik, an epitaph on a goose, a worthy com-
and aptitude for learning, was smitten with the thought that he was degrading himself out of his proper sphere; and one starry night, when, as he was driving home with him from a tax-collecting expedition, he turned the conversation on the heavenly bodies, and the boy, then aged thirteen, who had just been reading Batholomew's 'Philosophy for the Unlearned,' discoursed with fluency of things which Branting had never heard of, this feeling became too strong to be kept under. Lars Gustaf, the elder brother, was then aged eighteen years, and had become an officer with nine children. Branting wrote off to the captain in March, 1798, to say that he felt it a sin to keep such a boy as Essias from study, and to propose that he should be admitted to share, with the captain's boys, the instruction which the Ldwenhjelm family had long consoled and, the whole course of the young poet's life was changed. "I now began," he says in an autobiographical notice, written in after-life, "to study Latin; the method adopted was the old and sound, and, in my opinion, the only right one, which may indeed seem tedious and tiresome, but in the end, by the greater certainty it gives, spare time instead of wasting it." He stated that he began French and English at the same time—French in Tegn6r, and English in Mr. Jefferys's Grammar, which he received from a lawyer. He began to learn Greek, and received lessons from the archdeacon of Malma, the residence of Captain Löwenhjelm, who bore the marks of the iron rod with which Tegnér used to threaten it, when enthusiastically shouting out in English one of his favorite passages, "the living tree is not known!"

In the next year the services of Lars were transferred to the family of Christopher Myrman, an iron-master at Rämen, near Filipstad, who made some of the best iron in Sweden, and was a man of learning as well as a man of business. "It was a school of eloquence this brother should accompany him, and they both soon became almost members of the family. Myrman had eight sons and four daughters: Lars was tutor of the four eldest sons; Essias became at the age of fifteen tutor of three of the children, and became the fourth of the family, whom he married some years later.

At Rämen they found an excellent library in the classical languages, and a good collection of Swedish, French, and English books, but not a single German book; it was at the period before the introduction of German literature into Sweden. Of Shakspere, however, there was only "Hamlet," ' which, strange to say," remarks Tegnér, "interested me very little. It requires, however, a riper age than mine to be thoroughly understood."

According to his own recollections afterwards, he in seven months after commencing the study of Greek, had read the 'Iliad' three times through and through, and "twice, besides going through Virgil, Horace, and Ovid in Latin. 'It seemed to those around him,' says Böttiger, in his biography, 'as if he had been born with the foreign languages in his brain, and it only needed a gentle shake to wake the slumberers into life." He made himself at the same time proficient in chess and skittles. Often when the girl came to light his fire in the morning she found him still with his clothes on continuing the studies he had pursued all night. In 1799, when he went with his three pupils to the University of Lund, he passed such an examination in Greek that he received the степени of the first degree. His want of means became important when at this time so pressing; though he was supported by contributions from Branting and Myrman, that he resolved to relinquish a learned career, but a life of adventure which he hoped in classical Latin, led Fortunat Nordberg, a friend of his and an apparently to assist him to continue the struggle. For some time he studied eighteen or twenty hours a day; he made proficiency in mathematics, as well as in other studies, by means of a private school of his own. "Mr. Böttiger," says his biographer, "had a firm respect for learning, he became remarkable for the awkwardness, reserve, and rusticity of his manners. A post as under librarian, and afterwards that of assistant-treasurer of the Stock Exchange, increased his income, and finally, in 1806, he was awarded the Royal Swedish Academy of Sciences' prize. his country, and in the cultivation of poetry, which he had commenced some time before, but which he prosecuted during this time with such success that he was finally hailed by common consent the first poet of Sweden living or dead. He first obtained any attention, was on a melancholy occasion—the loss of his brother Lars Gustaf, who died in 1802. His elegy on that event was inserted in the 'Transactions' of the Literary Society of Gotenburg, of which he received some sort of prize. It was in 1808 however when there was an alarm of invasion that he suddenly burst forth as a poet of the first order, by his 'War-Song of the Scandanavian Defenders,' or 'Local Militia.' 'This warlike dithyramb,' says Böttiger, against the old school of classicism and elegance, 'seems to have once so grand and beautiful had never before been heard from the Swedish lyre. The electric lines ran like wild fire through the kingdom, bearing testimony that the North now owned a Tyrant fully equal to him who sang against the Roman Sparta.'

Tegnér, who had won the prize of the Swedish Academy; it was a spirited outburst of indignation at the degeneracy of the modern Swedes, compared with their ancestors, whose sword he weighed so heavily in the balance of Europe. Tegnér, who visited Stockholm to receive the prize, became acquainted with a great part of its literary men, at a time of transition when the Phosphorists, headed by Palmblad (Palmblad, S. 2), the introducers of German literature into their country, were contending with Tegnér for the head of the school of classicism and elegance, whose chief literary representative was Leopold. Tegnér, who was thought by his youth and his genius, naturally to belong to the anti-classical party, excited some surprise by undertaking the defence of Leopold, which he afterwards followed up by dedicating to him his poem of 'Axel.' His consecration as a priest in 1815 gave occasion to a poem on that subject, which was afterwards surpassed by a poem of the same kind, his 'Nattvaraldarene,' of children of the Lord's Supper, a sort of religious idyl, in 1820. In the same year, 1820, some santo of his 'Frichtofo Saga,' a romantic tale of ancient Scandinavia, appeared in the 'Ijama,' a periodical published by the Gothic Society, of which Geijer (Geiger, S. 2) was the leading spirit. 'Frichtofo Saga,' became so popular that it was successively translated into all Europe, and the whole country in either of them emerged into fame. His reputation was enhanced in 1821 by the publication of 'Axel,' a brief poetic romance, still thought to be one of the best of his poems. 'Axel' marked its culminating point in 1824, by the completion of 'Frichtofo Saga,' which became at once the most popular poem that has ever appeared in Sweden. From the period of the publication of 'Axel,' if not before, the name of Tegnör was recognized as that of the undisputed head of Swedish poetry.

This period of Tegnér's life was brought to a close by an unexpected, and at least at the outset, an unwelcome event. In 1824 he received the intelligence that the clergy of the diocese of Wexio had presented his name to the king as that of a fit man to succeed the esteemed Bishop G. B. I., and that the king had been pleased to select him for that office. As a clergyman he had not been remarkable for gravity of demeanour, and the general impression was that an excellent Greek to be accredited to a body, would now be turned into a very indifferent bishop. These expectations were disappointed. From the time of his appointment Tegnér's life took a different course. He ceased to appear as a poet, and gave himself up to the study of ecclesiastical business, the study of theology, and the accumulation of its revenues, in which his early experience with Branting was said to be of use. Almost the only unepisodic episode we hear of for some years is that memorable day in 1829 when he presented the poetical crown to Ochsen- neus, the Auti of Schillier ('Gottlieb Geikie, S. 1'); and when, at the same time, he was active in the Swedish academy's promotion of the study of the vernacular, and in the cultivation of national poetry. He was not at this time devoted to the Church; and in his study "wallaced with fathers of the church and biblical commentators." Thirty-one new churches were built in his diocese during..."
his episcopate. At the dioces which he attended he was distinguished for his conservative principles and his opposition to what he called "Radicalism," at the time when his younger contemporaries were so ardently tending in the same way, suddenly broke with the conservative party, on account of its propensity to carry reaction too far. His old liveliness was still to be found in his private letters. In the Diet of 1834 financial affairs were the chief subject; he opposed the policy of his leader, and his behavior was unwell, he said, that he was as little able to comprehend financial affairs as a member of the Bank committee. "As for bilinguism," he added, "it is unnecessary to carry that with one to the Diet. When I go there, and it belongs to the order of the day," Tegnér was still looked upon with such favor by his order, that in 1839 he was one of the three candidates proposed for the archbishopric of Upsal. Next year, alas! he was the inmate of a lunatic asylum, and are of much the same character as written shortly before in a letter to one of his friends: "there runs a vein of madness in my family. With me it has hitherto broken out in poetry, which is a milder kind of madness, but who can give me the assurance, that it will always take that way?" A selection of some months in an institution for the insane at Schleswig enabled him to return in 1841 to his family, and partially to his duties, and he was even able to preach so lately as June, 1845, but as a sick man, supported by his wife. He returned to his house and his house. He lay on the sofa, in cheerful spirits, and passed his time in reading. "About him," says Bottiger, "was generally seen a pile of books of different sorts and sizes, from the old Greek folio to the last fashions of printing of the French and English, and Voltaire and Scott were never wanting." After a stroke of paralysis and still weakened health, he died without pain on the 2nd of November 1846, shortly before midnight and during a beautiful appearance of the northern lights. His wife survived him, and he left six children, one of whom, a daughter, is married to Professor Bottiger of Upsal. Bottiger is himself a poet, and one of his best-known pieces is a description of a little incident which occurred to the writer of this notice, when he was present with his witness during the emotions which a stranger evinced over a book he was reading, and afterwards finding the book lying where the stranger had left it, he took it up and found it was "Frithiof's Saga." Tegnér, as we have seen, had lost his father in 1795; his mother survived till 1836, when she died at the age of ninety. In 1822, when the king of Sweden, Bernadotte, was returning from a visit to Norway, he heard that Tegnér's mother lived in a village he was passing through, and he caused her to be summoned and told her she had given birth to a son of whom she and Sweden might be proud. The mother of such a son however had passed most of her life in anxious tending on another son. Seven years, and at least in an unguarded moment walked into a river and was drowned.

The works of Tegnér were collected and published in six volumes by his son-in-law Professor Bottiger (Stockholm, 1847-48). Nearly three of the volumes are occupied by his smaller poems, two by prose works, chiefly speeches, and extracts from letters, and a volume and a half by the larger poems, on which the reputation of Tegnér is chiefly founded, and by a biography of the poet, from which we have taken most of our details. The smaller poems are many of them occasional verses on subjects of slight importance, but some are vigorous and interesting. One of his earliest is on "Pitt and Nelson," both of whom are objects of strong condemnation, Nelson being called the "Tamerlane of the Sea;" another, remarkably well written, is a dialogue between England and France, vituperating each other, in which England has decidedly the worst of the fray. The sympathies of Tegnér seem to have been everywhere limited, his contempt for Germans and Germany is repeated, and it is interesting to find it in his writings praise of any country but his own, which, except on a tour for health to Carlsbad in 1833, was the only one he had ever seen, or apparently ever wished to see. Child of the old Swed, he even at the age of threescore and ten, in a speech delivered in England and America at mechaniches institutes, &c., and bearing on the same class of subjects—the benefits of education, the utility of particular studies, &c. Of the larger poems, "Frithiof," "Axl," and the "Christ of the North," there is undoubtedly an opportunity of forming almost as good a judgment as the Swedish. No foreign poet has been so fortunate as Tegnér in his English translators. Of "Frithiof" there are at least five versions, more in number than we have been able to name. Of several of them, all are good. The first, by the Rev. William Strong, published in 1833, is undoubtedly the best, but is still the work of a man of learning, and of an enthusiast for his original; an anonymous one, published in 1842, is, next to the Strong's, of 1833, it is apparently in part by Frye, who deserves more notice than he has met with; a third, by R. G. Latham, in 1836, though not equal to Latham's "Axl," is a fair representation of the original; a fourth, by G. Stephens, now Professor of English at the University of Oxford, was published at Stockholm in 1841, and accompanied by a letter from Tegnér to say that he thought it the best English translation of himself he had seen; a fifth, by Oscar Baker, in 1841, possesses considerable merit. It is possible that the English reader, on the perusal of some of these, may arrive at the opinion that the "Frithiof Saga" has been considerably overrated. The same conviction has been arrived at by several English readers, among others the writer of this article, on the perusal of the original. The poem of "Frithiof" has no deep paths, no vivid eloquence. Its general character is that of neatness and prettiness rather than anything superior. It sinks often into tameness, and never rises to sublimity. The story, which follows too closely the original saga, is the story of a young northern warrior who is enamoured of the sister of the two young kings, who is denied her hand by her brothers, who, in his indignant proceedings thereupon, accidentally burns the sacred grove of children and is carried off by a god to a warlike expedition, on his return finds his beloved married to an old king, who generously puts an end to his existence when he discovers he is in the lovers' way, and finally obtains the hand of the lady after having humbly expiated the sacrilege and the atrocity which he committed. This story is told in four-and-twenty cantos, of which some are as short as ballads, and each one is in a different measure, one in blank verse, another in hexameters, &c. That an epic poem would be improved by a variety of metre, was a proposition laid down long ago by Dr. Watts, if not before him; but this mechanical variety of four-and-twenty different metres, not one repeated, has somewhat of a childish appearance. Tegnér's poem of "Axl" is in what may be called the Byronic metre, and in tone and structure strongly reminds the reader of Byron's " Mazeppa," or which it was doubtless modelled. The story is slight and commonplace—a maiden who falls in love to the war child of the Lord of Lidenbrock, who, being in love distracted—but the spirit with which it is told atones for every deficiency. Those who are fond of "Mazeppa" are sure to like this poem, either in the original, or its excellent English translation by R. G. Latham. There are two others, one by Oscar Baker, who has also translated "Tegnér" and another in "Blackwood's Magazine." The "Children of the Lord's Snapper" has been admirably translated by Professor Longfellow, who has also rendered various passages from "Frithiof" and "Axl."

TEG.B. a family of Savann Reptiles. [SAURIANS.]

The following is a synopsis of the genera:

1. Throat with two cross-folds, with larger 6-sided scales between.

A. Ventral shields small, long, smooth. Tongue contractile.

1. Teius.—Toes 5-5. Femoral pores distinct. Two species.

2. Callopistes.—Femoral pores none. Toes 5-5. One species.

B. Ventral shields broad, smooth.

* Tongue elongated, sheathed at the base. Teeth compressed.

3. America.—Toes 5-5. Teeth 3-lobed. Six species.

** Tongue not sheathed, free at the base.

Dicrodon.—Teeth compressed transversely, bld.  
Toes 3-5. One species.

Acrantus.—Teeth compressed transversely, bld.  
Toes 3-4. One species.

II. Throat with a collar of large shields.

7. Acanthophaga.—Scales of back large, of sides granular.

10. Crocodilurus.—Scales of back equal, similar. One species.

This family is well-illustrated by the *Teius Teguixus* of the British Museum Catalogue. It is the *Lacerta Teguixus*, Linn.; it embraces the order of *Tortoises*, Dumeril and Bibron state that they ordinarily inhabit the fields and the borders of woods, although they never climb trees; but they also appear to frequent sandy, and consequently arid tracts, where they are said to excavate burrows, in which they lay themselves up for the winter. When, in their flight to avoid pursuit, they come upon a lake, pond, or river, they plunge in, according to D'Azara, to escape from the danger which menaces them, and do not leave the water till all fear of danger is past. These Lizards, observe Messrs. Dumeril and Bibron, have not, indeed, webbed feet; but their long and slightly compressed tail becomes, without doubt, under such circumstances, a sort of oar, of which they well avail themselves. D'Azara states that they feed on fruits and insects, and that they also eat serpents, toads, young chicks, and eggs. He also relates that they are fond of honey; and that in order to procure it without fear of the bees, they come forward to the hive with their tails, they give the hive a blow with their tail, till repeated attacks they weary out the industrious insects, and drive them from their home. For figure of the *Variegated Lizard*, see *Lacerta*.  

TENANT.—THE UNWILLING LANDLORD. The provisions of the statutes 4 Geo. II., c. 28, and 11 Geo. II., c. 19, and 57 Geo. III., c. 53, have been superseded by those of the Common Law Procedure Act, 1852; the landlord's remedy remains, however, the same, the procedure alone is altered. [*Exempt. S. 2.*] Besides the remedy given to landlords in certain cases by the statute 1 & 2 Vict., c. 74, another equally summary method of recovering possession of premises when they are held over by a tenant, is afforded by the action of ejectment in the County Court. This tribunal may be applied to whenever the rent or value of the premises does not exceed 60L, and no fine has been paid. [*County Courts, S. 2.*]

TENNANT, WILLIAM, was born in 1786 at the little fishing-town of Easter Anstruther, in the County of Fife, Scotland, and was educated in the town-school, where he had for a fellow-student the afterwards celebrated Dr. Chalmers. In 1799 he was sent to the University of St. Andrews, and in 1801 was a fellow of and aide for the classical languages from the instruction and lectures of Dr. Hill and Dr. Hunter, but circumstances prevented his continuance for more than two sessions. At an early period of life he had lost the use of his feet, and could only move by the aid of two crutches. He was thus precluded from most active employments, and in 1801 he became clerk to his brother, who carried on the business of a corn-

THE ELEPHANTPEA, *Triumfetta pulcherrima*.—This is a tall, showy, climbing plant, rising from the dry sandy soils of the Sudan, and is remarkable for its long, pale, slender stem; the flowers are large, white, and fragrant; the leaves are palmately compound, and the pods contain many seeds. It is cultivated in many parts of the tropics, and is said to be of great value as a food for cattle. It is also useful as a shade tree, and is often planted along roadsides and in parks. Its flowers are large, showy, and fragrant, and the seeds are edible. The plant is propagated by seeds and cuttings. It is a hardy perennial, and can withstand severe weather. It is also known as *Triumfetta pulcherrima*. It is a large, showy, climbing plant that is native to the Sudan, but is now widely cultivated in many parts of the world. It has long, slender stems that can grow up to 20 feet tall. The flowers are large, white, and fragrant, and the leaves are palmately compound. The pods contain many seeds that are edible. The plant is propagated by seeds and cuttings and is hardy and can withstand severe weather. It is also known as *Triumfetta pulcherrima*. TEX

of Arkansas; N. by the Indian Territory, W. by the Territory of New Mexico, S. S. W. by the Republic of Mexico; and N. by the Gulf of Mexico. Its greatest length from north to south is 700 miles; its greatest width from east to west, 800 miles. The area is 274,356 square miles. The population in 1850 was 212,592 (of whom 58,161 were slaves), or 0.96 to the square mile. This however does not include the Indians, chiefly occupying the hill country, who were in 1853 estimated by the Commissioner of Indian Affairs at 29,000. The federal representatives according to the Census of 1850 was 192,297, in which number three-fifths of the male population were included. According to the present ratio of representation, entitles the state to send two representatives to Congress, To the Senate, like each of the other United States, Texas sends two members.

Surfaces: Hydrography, &c. — The surface of so vast a country is as varied as are all the malariously described as comprising a low and level region, an undulating or prairie tract, and a hilly or mountainous district, answering generally to what have been called Southern and Eastern, Middle, and Western Texas.

The level region occupies the entire coast, and reaches 80 or 60 miles into the interior. For 10 or 12 miles inland the country is subject to inundation, but behind this swampy tract it rises imperceptibly for some miles, and then stretches away in a plain with a more or less undulating surface. This plain is from 10 to 30 feet above the water-courses, and with the exception of the low bottoms along the banks of the rivers, it is not subject to inundation. The tide, though it varies only from two to three feet, ascends the river by a distance of 45 to 60 feet, but the mean level of the sea is a straight line. The whole of the plain is wooded, with the exception of the highest tracts of land between the rivers, which are destitute of trees, and exhibit fine prairies. The forests consist of different kinds of oak, hickery, iron-wood, sugar-maple, and other useful trees, which are found in the southern states of the American Union. The whole of this tract is in process of conversion into an immense field, producing cotton, maize, wheat, tobacco, and every kind of plant which blossoms and thrives in the borders of the tropics; the sugar-cane flourishes here, but is not much cultivated.

The undulating country at the back of this plain, though naturally less fertile, has a more genial and healthy climate, and with moderate culture appears capable of producing almost unlimited supplies of corn, cotton, and tobacco, while the uplands afford vast and excellent grazing grounds, being covered with grass, which maintains its verdure throughout the year. This is the most productive and productive portion of the state. The country between the river-bottoms generally rises from them with a gentle declivity to an elevation of 200 to 400 feet, and presents for the most part an undulating surface, on which isolated hills of considerable elevation are distributed. The greater part of this tract is destitute of trees, which occur only in isolated clumps along the bases and declivities of the hills, and at considerable distances from one another.

Western Texas, the hilly and mountainous district, includes the southern portion of the Sierra Sagrancos, and a nearly parallel range on the east called the Guadalupe Mountains. This region is little known, being as yet left to the Indian tribes, chiefly Cumanchees, to the wild animals, and to the hunter. Many of the mountains have been said to rise more than 2000 feet above their bases. Most of the rivers of Texas have their origin in the mountain region, and American writers speculate freely on what may have been when the 'water-power' is fairly turned to account. Texas owes much of its great capability for agricultural purposes to its numerous rivers and the regularity of their course. Nearly all the rivers, even those which run only 20 miles, are navigable. The greatest part of these have been said to be inferior to the celebrated Georgian Sea Island cotton. Tobacco also thrives well, and is becoming an important product of the state. The sugar-cane florescences, but, as already noticed, engages very little attention from the Texas farmer. All the region is an abundant crops. Maize is the chief grain staple; two

The Red River, and which, flowing chiefly in a south-southwestern direction, approaches nearly the centre of Texas and the most fertile districts, and enters the sea after a course of more than 400 miles; and the Rio Trinidad, which, after a course of more than 300 miles in a south-south-easterly direction through a very fertile tract, falls into the Gulf of Mexico, where separate Texas from the Indian territory and Louisiana, are noticed under Louisiana. The Sabine has a length of 350 miles, and is navigable for 150 miles, and much higher, byfeed boats. Before reaching the gulf it expands into a lake 50 miles in circumference. The bar at its mouth has 4 feet of water over it at low tide.

There are several good harbours along the coast. The low coast is skirted by a number of long flat islands, separated from the main by narrow straits; but these are much exposed to the sea, and afford little shelter. The coast is sufficiently well adapted for vessels of moderate burden. The bar at the mouths of the rivers have tolerably deep water on them, and there is no part of the extensive Gulf of Mexico which has more or better harbours, bays, and inlets than those of Texas. There are no lakes of any importance in the state; and no canals have yet been constructed.

A southern Pacific railway is to cross Texas from east to west, and several other railways are projected, but none have been made. All the western roads are many of them well laid out, and in good condition.

Geology, Mineralogy, &c. — The geological features of Texas have been but cursorily examined. The mountains consist principally of tertiary and recent deposits. In the eastern portion of this district a considerable belt of Lower Silurian strata has been observed. North of this along the Saba River, carboniferous strata occur. Much of the centre and north of the state appears to belong to the cretaceous system of rocks; while the whole of the level region, and the low districts bordering the Gulf of Mexico consist of tertiary and recent deposits.

In minerals the state is believed to be very rich. Gold has been long known in the smaller streams of the western portion of the mountain district. Silver also occurs in the hill country, and the silver mine of Saba is said to have been one of the richest in America during the Spanish occupation. Iron ore appears to be very widely distributed, and is known to occur in the southern part of the state. Lead and copper have also been found in several places. Coal occurs on the Trinidad and Brazos rivers. Alum is obtained in two or three places. Salt occurs very extensively in salt springs and lagoons; large quantities being taken from the salt lake near the River Pothash and soda are also obtained in dry seasons near the salt lagoons. Asphaltum is obtained on the coast.

The climate of Texas varies according to the locality from tropical to temperate; yet, except along parts of the coast and the rivers where subject to inundations, the climate is said to be generally pleasant and salubrious—in some places eminently so. The summer heat is modified by refreshing breezes, which blow almost uniformly from the south. In the interior, except in the northern part of the state, Texas has a periodical winds: from March to November they are from the south, and little rain falls; the rest of the year mostly windless, and in December and January they are strong and keen.

The characteristics of the soil and productions have been noticed in speaking of the surface of the country. Cotton has now become the staple of Texas: it generally grows well and abundant. Tobacco is also found. The cotton is said to be inferior to the celebrated Georgian Sea Island cotton. Tobacco also thrives well, and is becoming an important product of the state. The sugar-cane florescences, but, as already noticed, engages very little attention from the Texas farmer. All the region is an abundant crops. Maize is the chief grain staple; two
The crops of fruit ripen well. The vine grows luxuriantly, and it appears probable that Texas will become a wine-growing country. The orange, lemon, fig, peach, nectarine, pine-apple, olive, paw-paw, plum, apple, gooseberry, and many other fruits of both southern and northern climates ripen in abundance. There are numerous garden vegetables of almost every kind thrive remarkably here. Among the indigenous plants are the yam-pa, or Texas teas-tree, the leaves of which yield an infusion which serves as an agreeable cheap substitute for tea; and the nopal, which is a favourite food of the chinchilla insect, while cattle and horses feed on its fruit and leaves, and its wood is used for making fences, and for fuel. The native wild flowers include many of the choicest varieties of the Alps and conservatory; among others are the dahlias, stellaris of every variety, geraniums, passion-flowers, trumpet flowers, perpetual roses, mimosa, and an endless variety more of the most brilliant hues.

The trees of live oak and cedar surpass those of any other state in the Union. The entire coast, the river bottoms, and the chief part of the eastern section of the state, are heavily timbered with pine, oak, sash, hickory, walnut, cedar, cypress, and other forest trees, often of noble size and substance; and forest islands occur all over the prairie country.

Horses and cattle form an important portion of the wealth of Texas, the rich prairies affording unlimited pasturage. Swine are abundant; and though the wild animals, once so numerous, are rapidly diminishing in numbers. Buffaloes however yet roam the wilds in herds of many thousands; as do also deer. Wolves and foxes are still numerous, and the black bear abounds among the same, and the antelope and the wild-buck are numerous in the woods. Mustangs are found in droves in the west and north; when domesticated, they are much prized for their fleetness. Moose-deer, antelopes, mountain-goats, racoons, opossums, rabbits, squirrels, and numerous smaller animals are also found. The wild-fowl, in almost interminable numbers and of the most various kinds, afford ample supplies of game to the sportsman; and there are numerous singing-birds, paroquets, mocking birds, wood duck, and the ordinary kinds, as cock, mullet, pike, &c., and of species not usually met with, as the red-fish (which gives its name to Red-Fish River, where it abounds), a fish of delicious flavour and large size, sometimes weighing 60 lbs., the gar-fish, and the alligator. The alligator is a large river reptile, which is said to measure several yards in length, and to resemble the alligator in shape, &c. The common alligator is met with of very large dimensions, in the lakes and the lower course of several rivers. Oysters, lobsters, crabs, and other shell-fish are taken all along the coast. Turtles abound in the bays and harbours.

Manufactures, Commerce, &c. — The manufacturing industry is chiefly that incidental to an agricultural state, the produce of the capital being invested in grain, and cotton, the staple and most valuable article of commerce. There are somewhat considerable iron-works, machine-shops, and carriage and harvest factories.

The direct foreign commerce, though steadily increasing, is not very great, most of the exports being made coastwise to New York, New Orleans, &c. The exports during the year ending June 30, 1833, amounted to 1,029,681 dollars, of which 948,918 dollars were of domestic produce. The imports during the same period amounted to 281,649 dollars, and consisted of 187,511 dollars in foreign vessels, and 125,915 dollars in foreign vessels. The total shipping owned in the state in 1830 was 3897 tons, of which 3509 tons belonged to the district of Galveston.

Austin City, the capital, is situated on the left bank of the Rio Colorado, in 30°. 28' N. lat., 97°. 45' W. long.; was popula- tion 623. It is merely a village, but it contains the state buildings, and supports two weekly newspapers.

Galveston, the port city, is the commercial capital of Galveston county, is situated near the east end of Galveston Island, about 200 miles S.E. from Austin; population, 4177. The harbour of Galveston is the best in Texas, and sixteenth of the best in the Union; it is large enough to accommodate six large vessels. The trade of Galveston is very considerable, and is steadily increasing. A regular line of communication by steam-ships is maintained with New Orleans. There are a few good public buildings in the city, and numerous warehouses, hotels, &c. Galveston Island is 10 miles by 1 mile, and about 2 miles wide. It was once a favourite lurking place for pirates, but is now thoroughly cultivated, and the residence of several wealthy farmers. During summer it is much resorted to by invalids.

Houston stands at the head of navigation on Buffalo bayou, 160 miles E.E.S. from Austin; population, 2396. Next to Galveston, Houston is the chief business town in the state, being the centre of a rich cotton district. There are several state buildings, churches, and schools. A wharf 500 feet long, with cotton press at each end, extends along the front of the city.

San Antonio, near the source of the river of the same name, 76 miles S. by S. from Austin, population 1848, is the chief town in the S.W. part of Texas, and on the ancient route to the Mississippi. North America. It contains several ecclesiastical edifices erected during the Spanish occupation, a large ruinous fortress, and other vestiges of its former possessors; also a United States arsenal and some modern structures.

History, Government, &c. — The state was formed a part of Mexico. For some years prior to that date the American colonists, an active, numerous, and united body, had been making every possible effort to prepare the way for a revolt of the Mexican colonies. In 1810, the hostileilities commenced in earnest. The Mexican government was unable to suppress the rising; and eventually the Mexican army, under General Santa Anna, the president of Mexico, was defeated at Jutiapa by the Texans, under the command of the American general Houston. Santa Anna was made prisoner, and, as a condition of his release, agreed to sign a treaty acknowledging the independence of Texas. The Mexican senate disavowed the authority of Santa Anna to make such a treaty, but no steps were taken towards enforcing a re-composition of Texas; and in 1842 the United States of North America formally admitted Texas into the Union as a sovereign state. This led at once to war between Mexico and the United States; but the former country was soon defeated, and in 1846 the conflict was ended by the treaty of Guadalupe-Hidalgo. The state is divided into 25 districts, each with a county-seat.

The constitution was adopted in August, 1845. By it the right of voting is vested in every free white male citizen who shall have resided in the state for one year. The legislature consists of a Senate of not less than 19 nor more than 33 (at present 21) members, who are elected for four years; and a House of Representatives, of not less than 40 nor more than 90 (at present 66) members, who are elected for two years. The state is divided into 25 districts, each with a county-seat. The revenue for the year ending October 1857, was $1,544,694 dollars, and the expenditure the same. The state militia is composed of about 18,500 men and 1248 commissioned officers. In 1850 there were in the state two colleges, having 7 teachers and 155 students, the public schools remaining 368 teachers and 7498 scholars.

(Cyathetters of the United States: Official Reports relating to Texas, &c.; Seventh Census of the United States: American Almanac; Marion, Humboldt, &c.)

THALARCTOS.

THALLOGENS, a class of Plants proposed by Lindley for those Flowerless Plants which are distinguished by the absence of an axial atom. It includes all the Cryptogamia, with the exception of Mars and Mosses.

THEIN, Common rail. 1.

THENARD, LOUIS-JACQUES, BARON, a distinguished French chemist, was born at Nogent-sur-Seine on the 4th of May, 1777. He went to Paris early in life, and became
a pupil of Vanquelin. He devoted himself with so much zeal and success to the study of chemistry that when he was only twenty years old he was appointed demonstrator of chemistry in the Polytechnic School of Paris. By his unusual industry and great knowledge of his subject he was at last made professor of chemistry in the College of France and in the University. In 1824 he received the title of Baron on the occasion of the coronation of Charles X. In 1833 he was made a member of the Academy, and in the same year received the first half of a prize of 20,000 francs for his studies on the stamens of the coquelicot. In 1837 he resigned his professorship of chemistry in the Polytechnic School, and in 1840 he gave up his chair in the University of Paris. Baron Thénard was one of the most successful of the greater chemical reformers of the 19th century. His separate works however are not numerous. One of the best known of his literary productions he published in conjunction with M. Gay Lussac; it is entitled 'Recherches physico-chimiques'. This work was published after the discovery of the metallic nature of soda and potash by Sir Humphry Davy. Numerous experiments on the subject of the action of the galvanic pile are recorded, and methods of obtaining potassium and sodium independent of galvanism are indicated. Other subjects of high scientific interest were discussed in this work, which served to give its authors the first position amongst experimental chemists. In 1813 M. Thénard commenced the publication of his 'Traité de Chimie élémentaire, théorique et pratique'. This work was a full introduction to the science of chemistry and has gone through several editions and been translated into German; the last edition was published in France in five volumes in 1838. The great contributions of Thénard to the science of chemistry are to be found in the scientific journals and transactions of science of his time. Of these there is a vast number, embracing the whole range of chemical science. There is indeed no branch of chemistry at which he did not labour, and there is no subject he has worked at which he has not left considerable light. He died in the month of June 1837, and was buried publicly in Paris on the 23rd of that month. For many years before his death Baron Thénard had withdrawn from the pursuits of chemical science. To the last however he took a deep interest in the development of the scientific institutions of France. He was an administrator of the College of France and of the Faculty of Sciences, and vice-president for many years of the Superior Council of Public Instruction; and he has contributed more largely than any other individual since the death of Cuvier to the development of the scientific institutions of France.

THERAPEUTICS. Under this head it is proposed to give an account alphabetically of some of the more important applications which have been introduced into the list of the 'Materia Medica' since the publication of the first Supplement to the 'Penny Cyclopaedia.'

Anamirta or Anamirta, the name of a genus of plants belonging to the order Rubiaceae, to which the plant yielding the Cocculus Indicus of commerce is now referred. It has the following characters: flowers dioecious, calyx of 6 sepals in a double series with 2-closed pressed bracteoles, corolla none; stamens on separate flowers united into a central column, dilated at the apex; anthers numerous, covering the whole globose apex of the column. The flowers with pistil are not known, but the fruit is a 1- to 3-celled drupe. The seed is globose, deeply excavated at the bulla, albumen flabby, oedylous very thin, diverging. The plant which yields the pericarp of Cocculus is the only species of this genus. It is a strong climbing shrub, and is met with on the coasts of Malabar and the Eastern Islands. It is called Anamirta Cocculus.

Anæsthetics, is the term applied to those agents, which, when being applied or administered to the human body produce either a local or general insensibility. Such agents act more especially on certain parts of the nervous system, depressing, if both of its power of communicating and perceiving, the sensation of the part upon which they are applied. The state of anaesthesia comes on in various forms of paralytic disease, and as such has been known and described by medical writers. Anaesthesia can also be produced by artificially producing states of paralysis of the nervous system brought on by what is called animal magnets. In this state of the system the anaesthesia is sometimes so perfect that surgical operations have been performed on persons whilst in it perfectly unconsciously. This was known previ-ously to the general introduction of anaesthetic agents during the performance of surgical operations generally. All narcotic medicines will produce conditions of anaesthesia, in which surgical operations may be performed without pain. During the action of alcohol on the nervous system it is capable of producing a condition of insensibility without the knowledge of the patient. Although these circumstances have been generally known, it was not till about the year 1847 that any attempt was made to introduce anaesthetic agents as means of rendering all surgical operations. About this time two gentlemen in America, Drs. Morton and Jackson, made experiments on human beings with the nitrous oxide (laughing gas), and found that a state of insensibility could be produced under which surgical operations might be performed. The effects of this gas in producing excitation of the nervous system had been made known by the experiments of Sir Humphry Davy, and its peculiar action was often exhibited in the lecture-room of the chemist. It was also known that sulphuric ether produced remarkable effects on the human system. The merit, however, of the application of these remedies to the production of insensibility during the performance of surgical operations is due to Drs. Morton and Jackson. Having discovered that ether was much preferable for this purpose to nitrous oxide, they made known the important fact, that under the influence of this agent an insensibility might be produced under which persons might undergo the most severe operations without injury to their health. This announcement was speedily made known, and in the course of a few months the facts were realised in all parts of the world. In London the action of this agent was first tested in surgery. The action of ether, and the best method of administering its vapour, was investigated by Dr. John Snow, who in September, 1849, published a work on the 'Inhalation of the Vapour of Ether.' After the successful experiments with ether it was found that other agents similarly constituted acted in the same way upon the human system. This subject was investigated with great success in Edinburgh, and led to the discovery by Dr. Simpson of that city, that chloroform has equal powers to ether, and is administered both as fumes and as liquid, more safely and efficaciously than even ether. From this time chloroform became more generally used, and is now the substance which is generally employed for the production of artificial anaesthesia. After this Dr. Snow showed that amylene was capable of producing the same effects as chloroform. Whilst Dr. Richardson has shown from experiments on living animals that the dust of the common puff-ball, Lycopodium giganteum, which had been used by Apuleius as a narcotic in ancient times, had also the property of producing insensibility. These agents appear to act entirely through the nervous system, and according to the time employed in their administration will be their effect on the nervous centres. The first effect is to paralyse the conscious faculties; it is the brain, and a kind of intoxication comes on in which the patient is excited, the intellectual powers are deraigned, and the person acts as though drunk. This effect is produced much more quickly by the vapours of the above mentioned substances than by drinking alcohol, it also passes off much more rapidly. It was to this action more especially that the effects of the nitrous oxide and ether were confined previous to the discovery of their anaesthetic properties. The next effect is that the spinal cord is paralysed, in, the effect extends from the brain to the cerebellum, and this organ loses the power of regulating the movements of the body. This effect on the body is also produced by the drinking of alcohol. As the vapour continues to act on the system, the next nervous centre affected is the spinal cord, and the functions of sensation and motion immediately under the control of this part of the nervous system, are more or less affected. It is in this stage that consciousness is lost, if however recovery of some of the above sensations is not entirely lost, and the individual is pronounced in a state of anaesthesia. In this condition animal life is held in abey-ance, and the body is insensitive to all external agents. There is still however, a sufficient amount of nervous energy left, for though the heart beats, the lungs perform their functions, and other actions essential to life are carried on. These functions are, however, under the influence of these anaesthetic agents, and should too large a dose of them be administered,
they cease, and death ensues. This is one of the accidents to which the employment of these remedies is exposed, and against which the greatest precaution should be employed.

Dr. Snow, who has practically studied the agency of these remedies more extensively than any other writer, divides the action of ether into five stages. "In the first degree the person experiences various changes of feeling, but still retains a correct consciousness of where he is, and with his actions and reactions in voluntary movements. In this stage the patient's feelings are generally agreeable, often highly so. In this stage it is not practicable to perform operations without a certain amount of pain. When, however, persons have experienced the effects of the inhalation of ether, they return to this stage, and are free from the pain of an operation, whilst their consciousness has sufficiently returned to enable them to know what is going on. In the second degree, the mental faculties may be exercised and voluntary actions performed, but in a disordered manner. In this stage persons are often seized with a tendency to laugh, sob, or scream. They throw themselves about, their actions are insinuate, and not under the direction of the patient. The act of breathing is performed, and many operations not carrying the action of the anesthetic further than this stage have regarded it as useless. The patient may return to this stage from a further one, but it is most desirable that operations should not be continued in it. In the third degree there is no evidence of any mental function being exercised, consequently no voluntary motions occur, but muscular contractions in addition to those concerned in respiration may occur. There is sometimes great rigidity of the muscles, and the patient is not a very agreeable object to attend to, but not to utter any articulate sounds. "If this degree is well established, and if the patient has been detained in it at the same point, by inhaling at intervals, or by inhaling dilute vapour, operation may usually be performed without producing any other effect than a distortion of the features expressive of pain, and perhaps a slight moaning and an increased frequency of respiration, and in some instances a general rigidity of the muscular system." There is never an accomolulation of operations in this degree, even when symptoms of pain have been exhibited.

"In the fourth degree movements are seen, except those of respiration, and they are incapable of being influenced by the patient. All the muscles are stiff, and the limbs hang down, or rest in any position in which they are supported. The breathing is deep, regular, and automatic, and there is much snoring. In this degree the patient always requires a persevering vaporizing of the vapour in order of operation. It lasts seldom more than two or three minutes after the inhalation is discontinued. The integrity of the functions of respiration and circulation is not impaired. The pulse is distinct, and however much deranged in previous stages, is little disturbed in this; the stiffness of the glottis and pharynx is maintained, and the patient swallows without difficulty. In the fifth degree the movements of respiration and circulation become impaired, and every care should be taken to prevent the action of the vapour from arriving at this point, as death may shortly ensue.

With regard to the quantity of ether required, and the time necessary, Dr. Snow makes the following remarks: 'The experimental practice of giving 30 per cent. air with air mixed with vapour of ether in the proportion of 45 per cent. to 55 per cent. air, and breathing it easily and without obstruction, he usually commends about two drachms of ether per minute. It is not all absorbed, for the patient expired after the supposition of the trachees. At the end of the first minute he is usually in the first degree of asphyxia; of the second minute in the second degree; of the third minute in the third degree; and of the fourth minute in the fourth degree. If the inhalation is now discontinued, he commonly remains in this degree of asphyxia for one or two minutes, passes gradually back into the third degree, which lasts for three or four minutes, and then passes back into the second degree, lasting about five minutes, to give place to a feeling of intoxication and exhilaration, which lasts for ten or fifteen minutes, or longer, before it entirely subsides.'

The general effects of chloroform resemble closely those of ether. It is, however, a more potent remedy, and produces anesthesia more rapidly and certainly than ether. Hence it has been employed more generally. This substance was originally discovered by Liebig and D"ubene in 1831, and named chloroform. Dumas first pointed out that the liquid which had been called chloro ether, and chloride of carbon, was composed as follows, CHCl, and called it chloroform. Liebig and D"ubene, in subsequent researches, found that this was the chloride of the base formula. This substance is prepared according to the Pharmacopoeia of the London College of Physicians as follows:—Take of chloroform lime iv. lb.; rectified spirit os; water Ox; chloride of carbon broken into pieces, 2 lb.; discontinue the water into a retort, and then add the spirit, so that the mixture may fill only a third part of the retort. It is then heated in a sand-bath, and as soon as ebullition begins the heat is withdrawn. The liquid is then distilled into a receiver. A quart of water is then added to the distilled liquid and well shaken. The upper portion which subsides is then separated, and the chloride of calcium added to it, and frequently shaken for an hour. The liquid, which is called the chloroform, is a clear, limpid, and silvery glass receiver. It is a transparent colourless liquid having a specific gravity of 1.48. It boils at 140° Fah., and the density of its vapour is 4.5. It has a fragrant ethereal apple-like, and a slightly acid sweet taste. It is sometimes soluble in alcohol, and otherwise insoluble in water for its solution. It dissolves camphor, Indian-rubber, wax, and resins. It is not inflammable. This substance is sometimes given internally in doses of from five to ten minims, and acts as a stimulant sedative antispasmodic and anaesthetic.

Administered in the form of vapour as an anaesthetic, chloroform is much more powerful than ether. This effect seems to arise from its being more sparingly soluble in the blood than ether. The quantity of chloroform is sometimes prolonged. snow, "required to induce insensibility is less than one tenth as much by measure as in the case of ether. Viewed in this manner, it is more than ten times as strong; but to ascertain their comparative physiological power, and other is required to produce the same amount of insensibility in the adult, this would saturate 257 cubic inches of air at 60°, making it expand to nearly 300 cubic inches, which would be breathed in 12 ordinary respirations of 26 cubic inches each. The quantity of ether usually required to produce the same amount of insensibility in the adult, is about 75 fluid drachms; this would saturate 440 cubic inches of air at 60°, and increase its volume to rather more than 800 cubic inches, which would require 32 ordinary respirations to breathe it. We see, therefore, that 12 inspirations of air charged with vapour of chloroform are equal to 32 similar inspirations of air charged with vapour of ether, at the same temperature; and that, consequently, chloroform is nearly three times as strong as ether. In some instances, however, the effect of chloroform is less than this, for ether absorbs much more caloric than chloroform during its evaporation, thereby reducing the temperature of the air passing over it, and the sponge or whatever contains it, and hence limiting its own evaporation, in greater degree."—Edinburgh Medical and Surgical Journal,' No. 180.

It is on account of its greater strength that a larger number of accidents have occurred with chloroform than with ether. As chloroform is much less soluble in its administration, there seems to be no reason why chloroform should not be employed for the production of anesthesia. The usual method of administering this agent is to sprinkle a few drops upon a handkerchief and apply it to the nostrils of the patient, and the patient may take air into the lungs, which is saturated with the vapour of chloroform. During this operation care should be taken that a larger quantity of the vapour is not
The inhalation than will produce the fourth stage of anesthesia. By removing the handkerchief from time to time the patient may be kept in the third or fourth stage, according as it seems desirable. Although the administering of chloroform in the handkerchief is undoubtedly the most simple and convenient plan, it appears to be much safer to use an instrument called an inhaler by which the quantity administered can be regulated and controlled with certainty. Such an instrument was early used by Dr. Snow, and the accidents which have occurred have certainly been fewer when this instrument has been employed than with the handkerchief. In the inhaler employed by Dr. Snow the vapour escapes by opening the valve, the chloroform is surrounded with cold water, to limit the quantity taken up by the air, and the expiration valve of the face-piece is so adapted as to admit additional air to any extent to dilute the vapour still further. From an investigation of the fatal cases, and experiments upon animals, Dr. Snow has arrived at the following conclusions:

1. Chloroform vapour, if it be inhaled in large proportion with seething air, destroys life by paralysing the heart.
2. In smaller proportions, but long continued, it produces death apparently by the brain, and by interfering with the respiratory function. In such cases the heart is found to beat after the respiration has ceased.
3. Chloroform vapour, if it be blown upon the heart, paralyses it immediately.
4. Atmospheric air loaded with from 4 to 6, or even 8 per cent, of chloroform vapour may be safely administered, inasmuch as that mixture will not act directly upon the heart, but only through the influence of the normal functions of the body. The average time occupied in producing insensibility is from three to four minutes.

In cases where an over-dose of chloroform has been administered, the only remedy which appears to offer a chance of relief, is artificial respiration. Where the muscles of the tongue become relaxed, and this organ falls back over the glottis, it should be pulled forward till the patient revives. It might be desirable to open the jugular vein in order to relieve the distension of the right cavities of the heart.

The cases in which ether was first employed, and in which it has since been recommended as an anaesthetic, are those in which operation is interfered with by nature, or by accident. There are no operations, from the extraction of a tooth to the capital operations of surgery, in which it may not be employed. At the same time it may always become a question in the mind whether ether is not preferable to the very slight and insignificant effects of the chloroform, and ether. The quantity of amylene consumed in Dr. Snow's inhaler was at the rate of rather more than a fluid dram in a minute, and in this way insensibility was produced. Although Dr. Snow successfully administered this remedy in several cases, he met with one fatal case, and has since abandoned its use.

Other substances are capable of producing anesthesia in the former vapour, but none of these have been generally employed.

(Snow, On the Inhalation of the Vapour of Ether, 1847; On Narcotism by the Inhalation of Vapours, Medical Gazette, 1849 to 1851; On Death from Chloroform, Lancet, 1856. Richer, Medicinae Therapeuticae Practicae, 1813, 1816.)

Artanthe elongata, the plant which yields the medicinal agent known by the name of Atanthe. This is the plant to which the order Picroceae, and the Piper is angustifolium of Ruiz and Pavon, the Piper elongatum of Vahl, and the Stephania elongata of Kunth. Although this plant has long been used by the Peruvians, it is not very well known in Europe, the root has been employed as a substitute for the alkaloid of the tree in British Guiana, where it is called Bibiru or Simi. This plant belongs to the genus Nectandra (Nectandra, &c. 1.), and to the order Lauraceae. It is a large tree 60 feet or
more in height, undivided by branches till near the top, and covered by an ash-gray smooth bark; the leaves are 6 or 6 inches long and 3 or 3 inches broad, nearly opposite, oblong, elliptical, slightly acuminate, coriaceous, smooth, shining, and obscurely notched on the upper side. Pannels few-flowered, flat withollowwhite; not including all think, oblong, without glands. The fruit is somewhat oblate, globular, and slightly compressed, 6 to 7 inches in circumference; the seed in each fruit, about the size of a wheat.

The heart used in medicine is the bark. It is derived from the trunk, and comes over in flat heavy pieces from 1 to 2 feet long, from 2 to 6 inches broad, and about 3 or 4 inches thick. The epidermis is brittle and of a grayish-brown colour. Internally the bark is of a cinnamon-brown colour. The fracture is rough and fibrous. The taste is bitter, astringent, and aromatic. The seeds also contain the beeberrine, on which the medicinal properties of the plant depends. The following is Dr. Macalani's analysis of the two-

The alkaloid beeberrine is obtained by decomposing commercial sulphate of beeberrine by ammonia; the precipitate is then dissolved in water, whilst still moist with moist hydrated oxide of lead, dried in a water-bath and exhausted rectified spirit; an alcoholic solution of beeberrine is thus obtained. The alcohol may then be distilled from the beeberrine. If this is heated with ether a part will be left underlying, which, though it is distinctly alcoholic, and called it beeberrine, but he now regards it as beeberrine in an oxidised condition.

When beeberrine is obtained from its ethereal solution, it is yellow, amorphous, resins-looking substance, but in the form of powder it is white.

The effect of the Bibeurrb bark is the same as that of cinchona. It is bitter and tonic, and possesses antiperiodic or febrifugal virtues. The alkaloid possesses the same properties, and from experiments which have hitherto been made by Dr. Macalani, it is not so powerful as the common cinchona, and it does not produce the headache, feverishness, singing in the ears, and other symptoms which are sometimes found to follow the administration of cinchona. In intermittent and remittent fevers, in neuralgia, and as a genuine tonic it has been recommended, and especially in those cases where quinine disagrees.

**Berirolletia.** (Berirolletia). CADEUM, LODGE OF. The preparations of iodine with the metals have many of them been found to be very efficacious in the treatment of disease both internally and externally. Dr. Garrod has recently recommended the iodide of Cademum for external application. "I had," he says, "previously felt the want of an agent containing iodine, and fitted for external application—not those usually employed, and having many objections. The free iodine, or iodine combined with iodide of potassium, as occurs in unguentum iodinii composition, P. L., is frequently too irritant in its nature, besides which its disagreeable odour, and the staining of the outside which it produces is often very objectionable.

"The simple iodide of potassium ointment, as ordinarily dispensed, is gritty in character, often to such an extent as to render it useless, and fit only for the more superficial applications. It is frequently becomes brown from liberation of free iodine; now, although these inconveniences may be removed by proper management and care as to the purity of the drug, nevertheless I am disposed to look upon the salt, when mixed with fatty substances, as not very readilys absorbed by the skin, and consequently not well adapted to produce the peculiar local effects of iodine which is often so advantageous to obtain; for it must be remembersoned that iodine is (not always used simply for its rubefacient or covering properties.

He adds, that the iodide of cadmium is not open to these objections. Mixed with eight parts of lard it forms a perfectly white and soft ointment, which produces but little local action upon the skin, and appears to be readily absorbed when properly applied with friction.

Dr. Garrod recommends this ointment in enlarged seco-

foldulous glands, in joints affected by chronic inflammatory disease, in various cutaneous diseases, and chillblains.

The iodide of cadmium crystallises in white 6-sided naecous tables, and is soluble in water and alcohol.

Cynoemic Acid has been recommended by Mr. Marshall as an escharotic and demulcent, and it is to be observed that in the case of jaundice, which is so frequently attended with jaundice, it is an useful and powerful remedy. He recommends 100 grains of the crystallised acid in an ounce of distilled water. In the 'Record of Pharmacy and Therapeutics' the following account of the application of this solution is given:—

"The solution is best applied by aid of a pointed glass rod, or, where a large quantity is needed, by means of a small glass tube drawn to a point. Only so much should be applied as will saturate the diseased growth, avoiding the surrounding healthy mucous membrane; for although the solution is not sufficiently powerful as an escharotic to destroy or even vesiculate the mucous membrane, it may give rise to an unnecessary amount of subsequent inflammatory action. A solution of iodine as small as which no serious consequences have been found to ensue. Any superinfectious acid may be removed by a piece of wet lint. The first effect of its application to the warts is to produce a slight smarting pain. If, however, any ulcerated surface is present in the part, or the wart is already more lasting, but not so acute and intolerable as that caused by the nitrate of silver, or by nitric acid, with or without arsenious acid. After a short time the pain passes off, but the discoloration continues, and this process is accompanied by an evident diminution in size. The best immediate dressing to the parts is dry lint, as that does not dilute the strength of the chronic acid solution, and is at the same time clean. Afterwards the lint should be changed twice daily, or, what appears to be better as a check to any inflammation, the parts may be washed with a solution of lead, and dressed with lint moistened in the same.

"In most cases of warts, one application suffices, the cure being completed in from four to eight days. The extreme is arrived at very quickly, and not so powerful as any sublimate or iodine, and it does not produce the headache, feverishness, singing in the ears, and other symptoms which are sometimes found to follow the administration of cinchona. In intermittent and remittent fevers, in neuralgia, and as a genuine tonic it has been recommended, and especially in those cases where quinine disagrees.

**Cud Livers.** Cud Livers Oil is an oil obtained from the liver of the common cod, Gadus Morhua, Linnaeus. This, and other oils from fish, have been for a long time popular remedies amongst people living on the sea-shore, especially those engaged in fishing. In 1785 it was recommended by Dr. Parvis as a remedy in chronic rheumatism, and in 1809 Dr. Barclay stated it was a popular remedy in many parts of Lancashire. In 1841, Dr. Bennett, of Edinburgh, wrote a treatise on the 'Oleum Jecoris Ashii,' recommending it especially in scrofulous diseases.

Although this oil is named after the Cod, from the liver of which most of the oil is frequently and abundantly obtained, other fish yield oil in their livers and adipose tissue with which this oil is frequently mixed. The oil sold in England usually comes from Newfoundland, where it is obtained by distillation of the livers of the innumerable codfish which are caught in that sea and exported to the country. As it comes into the market it is usually of a chestnut-brown colour, and has a fishy smell. It is now, however, subjected to a preparation, by which its colour is almost entirely removed and it is rendered a pale yellow. Although more agreeable to the taste, it does not appear that its therapeutical properties are improved by this process. The following is Dr. De Jod's analysis of the three kinds of oil which are to be found in the shops of London:—

young children who will not take the oil, cream has been substituted with advantage.

In the case of rheumatism and scrofulous swellings the external application of the oil has been attended with advantage.

The friction of the whole body in cases of phthisis and scrofulous diathesis has also been strongly recommended by Dr. Lambossy.

When other remedies are employed in conjunction with cod liver oil, they may be added to this substance, and many preparations of this kind are kept ready for use by the practitioners. Such an objection has been urged against these compounds that if kept long the oil becomes rancid, and decomposition of the medicines take place. They are therefore best prepared extemporaneously.

Degenerators and Disinfectors. Although these terms are frequently used, the synonyms given have different meanings. Degenerators are substances which deprive decomposing animal and vegetable substances of their disagreeable smell; whilst disinfectants are agents which have the power of destroying the infectious or contagious properties, more especially of animal poisons. Many substances which have the power of effecting the first object, do not attain the last; and it is important to know that frequently when a foul smell is removed, an animal poison may yet remain which, whilst it may not be disagreeable to the sense, is not attended with any smell at all, as those of the small pox, typhus and scarlet fever.

One of the most powerful degenerators known is chlorine. This arises from its affinity for hydrogen gas which enters into the constitution of those gases which occasion the smell. In order to affect the sense in a disagreeable manner, as subpho-

Although this oil has been recommended in a variety of diseases, and has been administered in a most injudicious manner, in all kinds of disorders, the cases in which it has proved most successful are those of a gouty, and rheumatic, and scrofulous character. It has been found especially serviceable in the rickets of children, and in cases of phthisis. When first given it produces nausea, indigestion, and even vomiting; but, when persevered in, it is usually not attended with any unpleasant symptoms. In order to derive benefit from its use, it must be continued for several weeks, and even months. One of its most striking effects is in cases where emaciation has set in, is its tendency to produce plumpness and to increase the nutritive processes in the system. Cases are recorded in which persons have increased several pounds in weight in the course of a few weeks under the use of this remedy. Whilst this increase of weight is going on, there is increased tone and vigour in the system, and persons frequently gain considerable strength under its influence. In cases of phthisis many of the more urgent symptoms are relieved by its administration, and sometimes the progress of the disease has been entirely suspended.

The dose at the commencement should be half an ounce three times a day, which may be increased to one or even two ounces, should the stomach be able to bear it. It is given on coffee, milk, or peppermint-water. A small quantity of common salt taken before and after the oil will sometimes cause it to agree when other means have failed.

The nature of the action of this oil has been much debated by medical practitioners. Whilst some are inclined to regard the small quantities of iodine and bromine it contains as the active agents, others attribute its effects to the oily acids, which it has in common with all other oils. It is well known that oil plays an important part in the development of the albuminous tissues, and is universally present in the eggs of the lower animals, and it is supposed that its influence is exerted in the system in cases of scrofula, or when the adipose tissue is manifestly deficient it has an effect on the nutrition of the tissues generally. If this were the case, other oils ought to act in the same manner, and to a certain extent this is true, as it has been found that other animal oils, and even vegetable oils, exercise a similar effect. At the same time, it has been found that cod liver oil is more digestible and less liable to disagree with the stomach than other oils, and it is consequently used in preference to all others. Anolegious diet has been found, however, a valuable adjunct to the use of the cod liver oil, and in

THE
ammonia-like compounds by that of a powerfully fixed alkali. The manganites and permanganates, on the other hand, destroy the smelling substances completely; containing, as they do, a large quantity of oxygen, the very agent which consecutively effects all natural disinfection, and give rise to an actual process of combustion, in consequence of which the cause of the odor or putrefaction is permanently removed. They resemble, in this respect, the alkalis and chlorides of lime, chlorides of lime, the action of which is likewise permanent. The hypochlorites act with less energy and rapidity than the manganites, and are in this respect inferior; but they have an advantage over the latter by their ability to diffuse the substances, in this manner odorous and putrefactive substances which are diffused in the atmosphere. But as the chlorine evolved is frequently found objectionable by, and injurious to, patients, it would be important to ascertain whether the same effect could not be accomplished by exposing the contaminated air to the action of extended surfaces of solutions of the manganites and permanganates, either contained in shallow vessels, or diffused over sheets of wire gauze.

The manganites and permanganates have, moreover, the advantage of possessing peculiar and strongly marked colours, whereby they are readily and safely distinguished from other compounds. In consequence of this marked colour they can be employed as a means of disinfecting and securing the natural sterility of substances by the instinctual and correct use of hypochlorites, or of metallic salts, are scarcely possible with the manganites and permanganates, which are, moreover, in themselves comparatively innocuous.

The granules of permanganate of potash in a pint of water has been of much service as an application to phagedenic ulcerations, and to sloughing sores in various parts of the body. It has also been found particularly beneficial as an application to cancerous sores, where the smell is sometimes very offensive.

Where clothes, bedding, and other materials have been in contact with poisonous effluvia, one of the most powerful disinfectants is heat. The application of heat to such articles may either be effected by subjecting them to the action of boiling water, or exposing them to heat in ovens or closed vessels constructed for the purpose.

(See Minute of Information on Disinfection and Deodorization, published by General Board of Health, 1857.)

PHOSPHORUS. [Physic, Practice of, S. 2.]

HYDROPHOROUS ACID is a compound of phosphorus and oxygen, in the proportion of one equivalent each of them. It may be prepared by the decomposition of phosphide of benzol, by exposing it to the action of the alkalis and oxides of the metals, forming hypophosphites. These substances have lately been introduced into medicine as a remedy for pulmonary consumption. In a paper presented to the Academy of Medicine, in Paris, Dr. Quinault has proposed the use of a solution of hypophosphorus acid as a method of commencing phthisis, which he had treated with these remedies. Out of this number he states that nine recovered; in eight the evidences of disease disappeared; and in eleven, much improvement took place, and eleven died. Dr. Churchill believes that the immediate cause of tuberculosis is the decrease of phosphorus in the system.

The specific remedy, he says, "of this complaint consists in the employment of a preparation of phosphorus which has been converted into phosphoric acid by immediate assimilation, and the second of being at the same time in the lowest possible state of oxidation. The hypophosphites of lime and soda are the salts which have hitherto employed these two characters in the most complete manner. Either of these salts, administered in doses varying from ten to forty-five grains per day, may be used in the treatment of phthisis. The highest dose which I have given to adults has been fifteen grains per day."

These preparations have a direct action on the tubercular disposition, and dispel with a really wonderful rapidity all the symptoms which characterise the disease. When the morbid deposit which is the special result of the disease is obliterated as the only incident, and does not take place too rapidly, the tubercles are removed by absorption, and disappear without leaving any trace. When the deposit is ole of dose, and the softening has reached somewhat a higher degree, the breaking down process may continue in spite of the treatment, and the issue of the case will depend on the pathological peculiarities of the lesion, on its extent, and especially on the presence or absence of complications. I have made several unsuccessful attempts to meet this local mischief by means of inhalations of several substances, but I have obtained no favourable results except such as were owing to the general treatment.

The physiological effects which I have observed during the administration of the hypophosphites of soda, lime, potash, and ammonia, prove that these salts have a double action. On the one hand they immediately increase the principle (whatever it may be) which constitutes nervous power, and, by increasing it, still further and very much, their great breeding agents, far superior to any hitherto known. These preparations possess in the highest degree all the therapeutical properties attributed by former observers to phosphorus, and are devoid of the dangers which have almost consigned this substance to oblivion. It cannot be doubted that hypophosphorous preparations will henceforth rank foremost in therapeutics."

The salts of hypophosphorous acid can be prepared by adding the bases to a solution of the acid in water.

Hyposphorite of Potash occurs in the form of a white opaque powder, readily soluble in water and in alcohol. It is very deliquescent, and ought to be kept in stoppered bottles.

Hyposphorite of Soda crystallises in nacreous rectangular plates. It is a less deliquescent salt than the last, and dissolves readily in alcohol and water.

Hyposphorite of Lime crystallises in rectangular or square-sided plates, which are not deliquescent, and possess a bitter taste. It is perfectly soluble in water and is the most convenient form for administering the hypophosphites.

Hyposphorite of Ammonia has a similar appearance to the lime-salt. It is, however, deliquescent in the air. When heated gently, it gives off ammonia, and leaves hydrous hypophosphorous acid.

IDANORM, a compound of iodine, and the compound radical formyl. It was discovered by Scullas, and has recently been investigated physiologically and therapeutically by MM. Moretin and Humbot. It is a solid body occurring in pretty scales of a sulphur yellow colour, friable, not to the touch, of a persistent aromatic odour, with a mild and uncorrosive taste. When this substance is administered to animals, it drives them from smaller doses than of iodine, and exhibit symptoms of great depression and exhaustion. The symptoms of depression are followed by convulsions, contractions, and other effects upon the nervous system. After death they exhibit no signs of any marked lachrymose action.

The authors above mentioned suggest that this remedy may be employed in all cases where iodine is indicated. It is more rapidly absorbed into the system than iodine, and produces none of the local irritations which have been observed by those who have employed this remedy in small doses, from its soothing properties in neuralgic disorders. They have also employed it with success in goitre, scrofula, rickets, and syphilis. The dose is from half a grain to eight grains in the course of the twenty-four hours.

Kosso or Kvasso, the Abyssinian name for the flowers of the Brayera anthelmintica, a plant belonging to the natural order Rosaceae. The Kosso has been recently introduced into Europe by Dr. Brayer, from Abyssinia, and is of the highest value. It has been known in Abyssinia upwards of two centuries, as an anthelmintic, and has been mentioned by several writers. The plant which it yields it has been named after Dr. Brayer, a Jewish physician who resided a considerable time at Constantinople, and having had opportunities of witnessing the anthelmintic properties of this plant, brought some of it to Paris in 1823. On being sent to Kunth, he found it to be a new genus of plants belonging to the order Rosaceae.

The Brayera is an Abyssinian tree twenty feet in height, with round rusty tonentose-villose branches, marked by the annular electricities of the fallen leaves. The leaves are crowded, alternate, and sessile at the base of the petioles. The flowers are oblong, sessile, villose at the margin and on the nerves of the under surface. Stipules adnate to the petiole. Flowers dioecious, small, and greenish, the calyx with the tube bibracteate at the base and turbinate; throat constricted internally by a mem-
branched and produced a few leaves on the stem. It is a plant of the genus 
Tetraneuris, a species native to the Alps. The flowers are small, white, and 
petals are thin and translucent. The leaves are narrow and linear.

The plant grows in the Pyrenees and Alps, and is cultivated in France. 
Dr. Wettstein, a botanist, described the plant in a paper published in 
1854. He noted that the flowers are small and delicate, with petals that 
are thin and translucent. The leaves are narrow and linear. The plant 
is a member of the family Ranunculaceae, and is commonly known as 
Tetraneuris acaulis.
ridges 3, only dorsal; vitre, one to each dorsal furrow, and two to the laterals; albumen, thin flat.

N. Assafetida, Falconer: Radical leaves 3-parted; segments, bipinnatifid with oblong-lanceolate, obtuse, dentate lobes. Root of the plant is tuberous, taprooted. The pith, increasing to the size of a man’s arm or leg, covered with a blackish coloured bark near the top with many strong rigid fibres; its internal substance white, fibrous; abounding with a thick milky juice, which has an excessively strong odour, and is surpassed in two yards high, with one more, six or seven inches in circumference at the base, smooth, radical leaves nearly two feet long. The fruit is flat, thin, reddish brown, like that of a prapin, only rather longer.
THIERRY, JACQUES-NICHOLAS-AUGUSTIN, the distinguished historian, was born at Blois on May 19, 1793. In 1803 he commenced his studies in the college of his native town. He entered the military school, and in 1813 he became a teacher in a provincial school. In 1814 he went to Paris, enlisting himself as an adherent of the socialist principles of the Count St. Simon, of whom he became the friend and associated contributor to the publication of 'Les Rapports et Correspondances.' He however shortly penetrated the fallacy and shallowness of his master's doctrines, abjured them, and became with Comte and Duroc the editor, in 1817, of the 'Censeur Européen,' as a consequence of which it was believed that he first formed the theory of the continued existence of two classes in England— the Norman masters and the Saxon servants,— whose successive struggles he traced down to the time of Charles I. In an essay in this paper, and which, with much perplexed ingenuity, he pursued his course; but on receiving several other letters of disapproval, the editors wished him to vary his subjects. This he declined doing, and he ceased his contributions in January 1821. From that time he turned to his historical studies. However, he had to pursue his increased difficulties as approaching blindness rendered him unable to read, but he bore the deprivation with philosophical calms. In 1822 he published his 'Histoire de la Conquête de l'Angleterre par les Normands,' a work which, despite his false theory of the ever-enduring difference of classification of the two races, is of a high merit, as displaying great power of acute discrimination, the result of vast labor digested by a well-regulated mind, with great ability detected under the severities of the time, and an animal style. It has gone through many editions and has been translated into English and German. In 1827 he issued his letters from the 'Courrier Français' in an extended, and collected form under the title of 'Lettres sur l'Histoire de France,' which have also been translated into English. In 1828 a nervous disorder, added to his now rapidly falling sight, occasioned his being sent by his medical adviser to Évry, near Théméricourt, on the Yèvre, the sequester of the sequestered. While residing here for nearly two years, he was elected a member of the Académie des Inscriptions et Belles-Lettres, and was created a member of the Legion of Honour, of which he was appointed its office. The years 1831 to 1835 he passed partly at the warm baths of Lourmarin, and partly at Voseli in Haute-Saône, during which time, with the assistance of his brother, he composed his 'Dix Ans d'Études historiques,' a series of excellent essays, the product of his previous investigations, which was published in 1835. At this time, he was called to Paris by Guizot, who was then minister of public instruction, who confided to him the editing of a 'Recueil des Documents inédits de l'Histoire du Tiers-Etat,' which forms a part of the 'Collection des Documents inédits de l'Histoire de France.' In 1840 he published his 'Récits des Temps Mérovingiens, précédés des Considérations sur l'Histoire de France,' to which the Academy awarded their prize, and of which there is an English translation. A collected edition of his works was published in 1855. He died May 21, 1856.

As an historian Thierry takes rank with Michelet and Guizot. Less profound in philosophical dissertation than Guizot, less eloquent and imaginative than Michelet, he excels both in the number of groups of large masses published and of seeing and presenting every point of interest or importance; he combines picturesque effects with minute knowledge; and his style is earnest and lucid though not striking. He was also the merit of maintaining consistently devoted to his vocation. While many French writers of eminence looked forward to political influence or employment as his reward—and many continued to attain them, too often by a sacrifice of their previous principles or principles of art held on every undeviatingly. His consolation under various afflictions he has himself stated: 'Blind and suffering, without and without interruption, I will give this testimony which from me no one will disbelieve; there is nothing more powerful, better than property, better even than health; it is a devoted attachment to a science.'

JULIE THIERRY, whose maiden name was Guizotfranche. To the town of Lyon, in January 1831, and was of service to him in his then state of total blindness. In 1836 she published 'Séances de Mours aux 18me et 19me Siboles, for which her husband wrote an introduction. She was also the author of a number of ool very essays in the 'Revue du Département.'

THOISINAMEIN. [Chemist, &c.]

THOM, JAMES, who acquired considerable temporary celebrity as a sculptor, was born in Ayrshire in 1799. He was brought up as a stone-mason, and taught himself the art of sculpture. He began with models of them were produced in great numbers. There is undoubtedly a good deal of humour and spirit in the figures, but they are rude and inartistic in conception and execution, as those who have no self-taught sculptor himself. He afterwards executed a statue of 'Old Mortality,' and several other works; but he appeared to be falling into comparative obscurity when, about 1836, the misconduct of an agent whom he had employed to manage his business, brought the 'Tan O'Shanter' and 'Old Mortality' in the United States, led Thom to proceed to America. Eventually he determined to remain in New York, where he found considerable professional employment. He also devoted some time to assisting the sculptor with his own designs, and became a tolerably prosperous man; but he seems to have gradually abandoned the use of his chisel. He died at New York on the 24th of April, 1850. The original figures of Tam O'Shanter and Souter Johnnie, are placed in a building attached to the Burns monument on the banks of the Doon; there are copies of them in England, and at Mr. Col's, Paterson, New Jersey. His group of 'Old Mortality' stands at the chief entrance of the Landmark City Park, New York.

THOM, WILLIAM, the weaver-poet of Inverary, was born at Aberdeen in 1799. At ten years of age, with barely the elements of education, he was bound for four years apprenticeship to a weaver, and during this time, as he narrates in his 'Tan O'Shanter,' his experience during this time, he had a wish to undertake Latin, but being 'defeated in want of time.' At the end of his apprenticeship he was engaged at another factory, where he worked for seventeen years, learned to play the 'Germant flute,' and to 'every Scotch song that is worth singing.' He married about 1829, had a family, and after some other removals settled for a time at Newtyle, near Cupar-Angus in Forfarshire. He was there when the great commercial failures in America occurred, one consequence of which was the cessation of employment for the poor hand-loom weavers. With a wife and four children, without work, in a neighbourhood where nearly all were as poor as himself, and in a country where poor-laws were not yet introduced, the sufferings of the family were extreme, and in a cold spring day, in 1837 they resolved to set off to walk to Aberdeen, in hopes that there might procure employment. Of this journey he has given a vivid and pathetic narrative. One child died on the way of illness in means of provision. He then obtained work, first in that town, and then at Inverary. In November 1840 his wife, whose health had been weakened by her late sufferings, died in childbirth. His new afflicts again drove him to poetry, realising Shelley's assertion that poets 'learn in suffering what they teach in song'.
He sent one of his compositions, 'The Blind Boy's Franks', to the 'Aberdeen Herald', where it was inserted with much commendation. It attracted the notice of Mr. Gordon, of Kincardine, who immediately relieved and patronised him. He had other poems by him, which were produced and admired, and he was brought to London, feasted at a public dinner, and received that sort of notice which has so injurious an influence in the case of Burns, a patronage that only enhances the bitterness of the fate to which its objects are almost inevitably consigned.

Thom returned to Inverary, resolving, he said, not to be too much elated by the applause he had received, but it was in vain trying to suppress its effects, and he finally gave the appearance of monographs on the distribution of animals in Europe.

THOMSON, ANTHONY TODD, was born in Edinburgh on the 7th of January, 1778. His father, by birth a Scotchman, but afterward became a naturalized citizen of America, where he held two lucrative appointments under the Board of Postmasters-General for the province of Georgia, and Collector of Customs for the town of Savannah. Having refused to take the oath of allegiance to the American government, on the breaking out of the Revolution he was compelled to relinquish his appointments, and returned to Edinburgh. Anthony Todd was born previous to this, whilst his mother was on a visit to Edinburgh. He received his education at the High School, Edinburgh. When a boy he was apprenticed to Dr. Lord Cockburn, which lasted till his death. His father destined him for business, but having obtained a clerkship in the Post-office, he was enabled by the leisure it afforded him to become a medical student.

He attended the lectures of Munro, Gregory, Black, and Dugald Stewart. In 1798 he became a member of the Speculative Society, and the companion of Jeffrey, Horner, Brouqham, and Lord Landsdowne. In 1799 he became a member of the Royal Medical Society, and in 1806, when he graduated in 1799, he left Edinburgh, and established himself in London about the year 1800. He commenced the practice of his profession in Sloane-street, Chelsea, as a general practitioner. He was a most active, but at first, slow, physician. In the course of a regular practice he was called into the midst of a large general practice, he found time to cultivate science and literature. He was mainly instrumental in procuring the enacting of the Apothecaries' Act in 1814. His first literary work was published in 1810, and entitled 'Conspectus Pharmacopoeiae.' He sold the copyright of this book for twenty pounds. In 1833 it was bought by the Messrs. Longman, for two hundred pounds. It has gone through fourteen editions. In 1831 he published the 4th edition in London in a very small quarto, which contained 546 pages. It contained a critical account of all the medicines and their compounds which were in use in Great Britain. It has been translated into several European languages, and ten editions have been published in this country. The searches into the materia medica he was impressed with the importance of the study of botany, and he was one of the first to give a course of lectures on this subject in London. In 1821 he published a first volume of his 'Lectures on Botany,' which contained many very valuable observations on the structure and functions of plants which have since become a part of the science of botany. In his observations, he made extensive use of the microscope, and may fairly claim to be one of those who appreciated the value of this instrument when its use was generally neglected. In 1826 he became a member of the Royal College of Physicians of London, and commenced practice as a consulting physician. In 1828 he was elected Professor of Materia Medica to the University of London; now University College. In this position he worked with great ardour at the subject of Therapeutics, and was one of the first to introduce the new substances discovered by the chemist into the practice of medicine. He formed here a very fine collection of specimens of materia medica, but the occurrence of a fire put an end to the collection in 1831. Three of these were devoted to the birds. He did not live to complete his work. He had been mainly instrumental in inducing the British Association to meet in 1832 in Belfast. In promoting this object he came to London in the January of that year, when he was seized with paralysis, and died in the course of a few hours. The manuscript of another volume on the 'Natural History of Ireland' was found after his death in a sufficiently advanced state to be given to the public, and this was published with a short memoir of the author by the late Sir Smith, Bart., in all the local institutions of his native town. He was president of the Natural History and Philosophical Society of Belfast, member of the Royal Irish Academy, and Fellow of the Linnean Society. William Thompson is a remarkable instance of a man who, by the devotion of average talents to one great object, succeeded in his work on the natural history of Ireland in achieving for himself a lasting reputation, and perhaps almost as much as he did for his species. The most valuable monographs on the distribution of animals in Europe.
he was engaged in preparing 'A practical Treatise on Diseases affecting the Skin,' which has since been completed and edited by Dr. Parkes. In 1846 his health first began to fail. He continued to give his lectures, with considerable interruptions, till the following summer, when he was obliged to retire into the country, and died of bronchitis at Ealing, June 14, 1848.

Dr. Thomson was a man of unwearied industry, and throughout his long career, pursued his labours with few or no interruptions. He was a man of varied attainments, cultivating literature as well as science; he was not an undistinguished contributor of literary articles to the Magazines and Reviews. He translated from the French, and edited, with a work by Mons. Salvarte, entitled 'The Philosophy of Magic, Omens, and Apparent Miracles.' His notes to this work were afterwards published in a separate form, and inserted in the 'Repository.' He also edited also an edition of Thomson's 'Seasons;' to which he appended a large number of notes, and a life of the author. He contributed many articles to the ' Cyclopaedia of Practical Medicine.' He was for many years editor of the 'Medical Repository,' to which journal he also extensively contributed. One of his last works was entitled 'Domestic Management of the Sick-room,' of which several editions have been printed. A sketch of his life, from which this notice has principally been obtained, is published with his posthumous work on 'Diseases of the Skin.'

THOMSON, THOMAS, M.D., a celebrated chemist, was born April 12, 1773, at Crieff, Perthshire, and received his early education at the parish school of that place. Afterwards studied at St. Andrew's and Edinburgh, and was a pupil of the celebrated Dr. Black. In 1802 he delivered a course of lectures on chemistry, and continued to lecture on this science for nearly fifty years. He was one of the editors of the 'Encyclopaedia Britannica.' From 1796 to 1800, and wrote the articles 'Chemistry,' 'Mineralogy,' &c., in that work. In 1802 he published his 'System of Chemistry.' He first suggested the use of symbols in chemistry, which was afterwards adopted by his contemporaries. He was one of the first chemists who recognised the value of Dalton's atomic theory, and devoted himself to its elucidation. He also at this time conducted for the Board of Excise a series of investigations on brewing, which formed the basis of Scottish legislation on that subject. In 1813 Dr. Thomson came to London, and started the 'Annals of Philosophy,' a scientific journal, which he edited till the year 1822, when he resigned it to his friend Mr. Richard Phillips. In 1827 this journal became merged in the 'Philosophical Magazine.' In 1817 be was elected lecturer on chemistry in the University of Glasgow, and the following year received the title of professor. This chair he held till his death, assisted in his later years by his nephew and son-in-law Dr. Richard Thomson. In 1833 he published 'Outlines of Mineralogy, Geology, and Mineral Analysis,' and in 1849 a work on 'Brewing and Distillation.' He died on the 2nd of July, 1852. His son, Dr. Thomas Thomson, is celebrated for his botanical knowledge; he has published an account of his travels in Tibet, and is now the superintendent of the East India Company's botanical gardens at Calcutta.

THREE RIVERS. [CANADA, S. 2.]

TIRIP, the name of the Statiche Armeria, Smith, now Armeria maritima. Armeria belongs to the natural order Plumbaginaceae. It is distinguished by the flowers being in a head contained in an inverted cylindrical sheath, and the capular fruit not bursting. A frequent plant in the dunes, growing on mucky and rocky sea-shores and on the banks of salt-water marshes. It bears transportation to gardens, where it is a favourite in forming the borders of flower-beds. It may be easily cultivated from other species by its linear 1-nervef leaves. It has rose-coloured flowers. Several varieties are described.

THEUREA. [Noswella.]

TIECK, CHERNISCHKA, 1756-1806, a celebrated sculptor, brother of Ludwig Tieck, was born in Berlin on the 14th of August, 1777. Having studied awhile under Schadow, he in 1798 proceeded to Paris, where he became acquainted on the 1st of January, 1800, he returned to Berlin, and afterwards went to Weimar, then a centre of literary and artistic activity. There he found Göthe a warm and most valuable friend and adviser, and whilst he not only assisted in the execution of the sculptural decorations of the new palace, but executed busts of Goethe, Voss, and Wolf, besides many of members of princely and noble families. In 1805 he went with his brother Ludwig to Italy, and carefully studied the great works of art there, maintaining at the same time by his numerous busts, &c., his independence as an artist. Here he became acquainted with Madame de Stael, and the crown-prince, afterwards King Ludwig, of Bavaria. For the former he executed a relique for the family sepulchre at Coppel, and ennobingly a bust of her and her son, and for the latter some busts of Broglic, Augustus Schlegel, and M. Rosenberg. For Ludwig of Bavaria he executed at various times busts of Ludwig himself, Jacobi, Schelling, Ludwig Tieck, Lessing, Erasmus, Grotius, Herder, Wallenstein, and several others, chiefly for the Kieler Dom. In 1812 he became acquainted with Rauch, and the two great sculptors ever after remained fast friends. He returned in 1819 to Berlin, where he established his atelier, and was elected a member of the academy. During the remainder of his life he was employed upon many of the public works, and was a prominent actor in the artistic movements in the Prussian capital. Among his productions were the friezes, the sculptures in the pediment, and other external decorations of the Theatrical Royal, the gallery of the Elector, the edifice of the cathedral in Berlin a series of fifteen seated marble statues of classical personages for the royal palace; a bronze equestrian statue of Frederick William at Krippen, besides several monumental works and statues. Tieck has been during the last thirty years extensively employed on the restoration of ancient works for the Royal Museum, in which institution he was director of the department of sculpture. He died at Berlin on the 14th of June, 1851. Tieck was not possessed of a manual dexterity, but an uncommon sagacity of mind, and revelled, but his chief strength lay in his memorial busts, many of which display great elevation of style and admirable chiselling. In his studio several eminent sculptors have formed, among whom perhaps the best known is Kiss, the sculptor of the Amazons. There are casts of some of Tieck's works in the Crystal Palace at Sydenham.

TIECK, LUDWIG, one of the most influential actors upon the modern literature of Germany, was born in Berlin, on May 31, 1773. At the universities of Halle, Göttingen, and Erlangen, he studied with great arcaud; history and the poetical literature of both the ancients and the moderns being his favourite pursuits. His poetical powers developed themselves early, but they took a direction opposite to the poetical. His moral sense and his general judgment, his feelings and opinions of what may be termed the Christian chivalry or romance of the Middle Ages, although his first efforts, 'Almamur,' a prose idyll, in 1796, and 'Alaunga,' a romantic drama, were poetical, save in a form of eastern locality. Both displayed great poetical ability, but he did not attempt verse, except in a few short pieces introduced amid the prose. In 1792 he produced the tragedy of 'Der Abscheulich,' (The Farting), also in prose; which, like most of his other dramatic pieces, is more laid for the closet than the stage. He probably himself began to perceive that his true strength lay in narrative, and in the same year he produced 'Das grüne Band,' a medieval tale of considerable pathos, with great truth of characterisation and psychological interest; and 'Abdallah,' an oriental tale, with little of oriental colouring, and of a ghastly terrifying character. He had made much progress in the study of English literature, particularly the drama, and he had formed a decided preference for the romantic character and scenery intended to be English, but they have a more poetic tone of the whole is more gloomy than most of Tieck's productions.

The six years, from 1786 to 1800, both inclusive, was a period of intense literary activity. During this time he visited Jena, where he formed an intimate friendship with the two Schlegels, Novalis, and Schelling; Weimar, where

Digitized by Google
he became acquainted with Herder; and Hamburg, where he married the daughter of a clergyman named Alberti. The intercourse with the above-named literary celebrities had much influence on his future course. While still adhering to the romantic school, his productions ambitioned a wider field. He continued to write tales, novels, tragedies, and comedies; but in embodying nursery tales, as in his 'Blumhart,' a play in five acts, 'Die Sieben Weber der Ältesten,' he displayed the earliest intimation of a turn to the_domestic, as in 'Leben und Tod des kleinen Röthkäppchen' (Life and Death of Little Red Riding Hood), a tragedy in three acts, he united much of the simplicity of the old traditions, with the added interest of poetical conception, a close adherence to a particular style, and a fine sense of the picturesque and of humour. Occasionally he took for his subject legends of a higher character, as in his 'Leben und Tod der heiligen Genoveva;' and in 1804, in 'Kaiser Oktavius,' a work which had been long expected, and which his countrymen consider as one of the most successful of his romantic productions. To this he has prefixed a long prologue, in which various characters are introduced to display the proaic element, and a poet, to whom comes Romnaene, a female, who describes herself as insinuous, joy throughout the world, and says that her father is Faith, and Love her mother. In this prologue, and in the following play, which is partly in prose, is found the most favourable specimen of Tieck's versification. It is not of the most careful construction; and there is little consistency in the line of his verses, or in the judicious poetical, the best examples of them are found in his prose. This line was followed out in subsequent works, as in 'Fortuna,' which however embodies a commendable amount of good-humoured satire on the various conditions of the estate. These pieces are styled by the Germans Art- Novels, to which belong 'Franz Sternbald's Wanderungen,' 'Phantasien über die Kunst,' and 'Zur/secenmessungen eines Kunstliebenden Klosterbruders' (Heart-throben of an Art-loving Monk), written in conjunction with his friend Wackenroder, in all of which he displays a love and knowledge of the beautiful, and elevated in art, a contempt for the self-complacency of affected connoisseurship, and a manifestation of Roman Catholic feeling, to which faith he for some time adhered about this period. Perhaps less distinctive as a class, as his previous tales had much of a similar character, were his 'Volksmärchen' ('Popular Legends'), such as the history of Heymon's Children, the 'Faë Magelle,' Melusine, &c., legends which are in German, and the 'Denkwürdige Geschichtstornik der Schildbürger' (Memorable History of the Simpletons), a sort of German version of our Men of Gotham; tales in prose, abounding in pleasant fancy, incident from which the author has not been unwilling to imbibe humour, and told with a simplicity and an apparent childish belief in the wonders related that give an indescribable charm to the whole. Upon yet another class he evidently bestowed more thought and labour. In the dramas, for the stage, that he has written throughout his productions, he has always endeavoured to interest and to instruct, and to please. In the 'Journey to Etna' (Tieck's 'Voyage to Etna'); in 'Prinz Zerbino, oder die Reise nach dem guten Gesuchsther' (Travels in search of Good Taste); 'Die verkehrte Welt' (The World turned upside down); and 'Leben und Taten des kleinen Thoma, genannt Dümchen' (Tom Thumb); in all of which he attacked with keen irony the low, material, anti-poetical notions of poetry advocated by learned pedants, and defended by implication, by example, and by occasional parodies on the classics, the theory of the German national school was, however, that Tieck was acquainted with the peculiarities of all the authors alluded to in that drama, would possess much interest for the English student. These pieces, independent of their critical merits, have an interest of their own from the variety of the characters, the genuine and humorous life of many of the characters, and from the skilful manner in which the events of this period, including most of those above-mentioned, were subsequently published together, under the title of 'Phantasius,' in a frame-work of a conversational party, to which the names of many of the characters. Many of the characters, introduced into this work, were first introduced as characters in Tieck's 'Voyage to Etna;' 'Don Quixote,' a very good one of Ben Jonson's 'Epicoene,' or the Silent Woman,' and a remarkably successful one of Shakspere's 'Tempest,' also belong to this period. In 1801-2, while residing in Dresden, he assisted F. Stein, who edited the new edition of the 'Faë Magelle,' to which he contributed some of his tales. He then lived for a time at Berlin, and next at Ziebigen near Frankfurt-on-the-Oder, seeming to enjoy a poetical leisure, during which he produced nothing but 'Kaiser Oktavius' of which we
unhappy fate of Canaues is pathetically related. In 1826 he also produced one of his most picturesque narratives, "The Torpe Dog," in the Cevennes is graphically told, but unfortunately was left incomplete. While residing at Dresden his evening circles became celebrated, at which his readings and the relation of his tales formed a principal charm, and which were eagerly anticipated by the German buffs. The stories he created were in the vicinity and could gain admission. In 1836 and 1840 he published his two latest novels—"Der Tischlermeister" (The Cabinet-maker) and "Victoria Accorumbones," both of which are among the most of his previous works of a similar character. He also took an active part in the management of the Dresden theatres. In 1840, on the accession of Friedrich Wilhelm IV. to the throne of Prussia, Tieck was invited to Berlin, an invitation which he accepted. Here he created the "Privy-councilor" and passed the remainder of his life partly in Berlin and partly at Potsdam, occupied chiefly with some theatrical productions, and in revising and correcting his works, which were published in 20 volumes at Berlin between 1826 and 1846. At various times he also edited Rovally's "Schriften," in conjunction with Friedrich Schlegel, 1802; Heinrich von Kleist's "Nachgelassenen Schriften" (Posthumous Works), 1826; Solger's "Nachtla und Briefwechsel" (Remains and Correspondence), 1825; and Reinhard Lenz's "Gesammelte Schriften," (Collected Works) in 1828. After suffering for some years from continued illness, born with wonderful patience and cheerfulness, he died at Berlin, April 28, 1835, leaving a name which may rest upon the record of his name in German literature, and no Englishman may reverence as that which in Germany is most connected with the popularizing of the fame of the great dramatic poet of England.

The Tila, a genus of Plants belonging to the natural order Orchidaceae. It has a 2- or 4-parted calyx; petals 3 or 4, olling acuminate; scales none, or very small; carpels 3 or 4, somewhat constricted in the middle; 2-seeded. The species are small glorious annual herbs, with spike-shaped and globose,eh umbilum places. The leaves are opposite. Flowers small, white, for the most part axillary. T. meccica is a native of Europe in many places, in dry, barren, sandy, and gravelly soil; plentiful in Britain on the most barren sandy heaths, and frequent in Norfolk and Suffolk. It has a stem branched and decumbent at the base; flowers axillary, sessile, and trifid. The plant is very minute, and of a reddish colour. The leaves are opposite, oblong, obtuse, concave above, connate; sepals oval, and by opposite, brittle-pointed. Petals nearly subulate, white, tipped with red. There are several other species, natives of North and South America and Australia.

TINALCOL [Boroqo AGLI].—The Tinalcol, a family of small Moths, which are remarkable for depositing their eggs among animal substances, on which their larvae afterward feed. They are thus constantly found upon clothing made of hair or fur, and are called Clothes-Moths. The family is thus defined—"Antenen moderate, slender, simple, pubescent beneath in the males; proboscis short; thorax rarely crested; body long and slender; wings entire, often narrow, mostly convoluted in repose. The caterpillar live in portable cases formed of various materials. These moths are often ornamented with very brilliant colours, the upper wings having gold or silver spots. The caterpillars make their cases of the substances on which they feed. The Adele make their nests of bits of leaves. The true Tines-cl themselves with the hair of the skins of animals and bits of silk. When too small, they stuff their cases and make them larger. Many of them burrow into skins, silks garments, &c., making cases as they proceed. They are widely spread, and are very destructive."

TIPON [SUFFOLDIUM].—TIPULIDE, a family of Dipterous Insects belonging to the tribe Agromyzidae. They have the antennae longer than the body, and not sheathed; eyes entire, ocelli obsolete; front of head beaded; proboscis short, ending in two large fleshy lips; body elongated; wings long, nervures numerous; legs long. One of the most common of this family is the species of Ctenophora, Pseudocella, and the species of Tipulids which are usually known by the name of Daddy-Long-Legs.

Laubreville divides this family into five smaller groups—Culiciformes, Gallihoes, Teriroides, Fungivores, and Florales.

The Culiciformes (Chironomides, Maquart) include those forms the pupae of which mostly dwell in the water, respiring by means of external tubes or filaments situated in front of the body. They have also the power of swimming, and are usually remarkable for their cleanly, beautifully objects for the microscope. The larvae of Chironomus plumosus are vermiciform, and of a blood-red colour, whence they are called Blood-Worms. [Chironomidae]

The Gallihoes (Oecidomyiides) include those species which form galls by depositing their eggs upon plants.

The Fungivores (Myagrophilous, Maquart) embrace an immense tribe of insects, of which some are uncapable of leaping by means of their hind legs. They are found in damp situations amongst various plants. They enter houses, and are found upon window-panes. They are also very partial to fungi, hence their name; and they are generally found in the vicinity of Botany and Pomology.

The Terriroides (Tipulides, Maquart) are the true Crane-Flies. The species of the genus Tipula are found in damp meadows in great numbers, especially in the autumn. The larva are white, with a blue spot on the back, &c., and occasionally do much harm. Mr. Westwood remarks that the male Daddy-Long-Legs is very quarrelsome, and often fights with his brethren of the same species.

The Florales (Bibionides, Maquart) are distinguished by having the body and legs shorter and more robust than the other forms. The species are small and their flight is slow and heavy. (Vide "Families of Insects," by TdcmorD.)
his poems had 10,000 subscribers; not long afterwards his fellow townsmen proposed to erect his bust in a public place, and it was only the reluctance of Tollens himself which prevented the intention from being carried out, when the subscription was already full. This popularity increased as he grew more advanced in life. On his seventieth birthday, the 24th of September 1850, the minister of justice, Mr. Nedermeijer van Rosenthal, waited on him at his house at The Hague, and was shown round the King of Holland, and present to him the insignia of commander of the order of the Dutch Lion, a very unusual honour for a literary man. A committee was then submitted to him the same day to offer him the Dutch order of the Lion of the Sea, as "Nederland zijnen geëerde Volksdichter" (Netherlands to its beloved national poet), and to inform him that a subscription had been organised, without his knowledge, for the formation of a "Tollens Fund," to commemorate his name by a charitable institution, the nature of which was to be left to his own choice. He died in 1856, surrounded by universal respect.

The shorter poems of Tollens, lyrical and narrative, are his chief title to remembrance. One narrative poem, De Overwintering der Hollander op Nova Zembla (The Wintering of the Hollander at Nova Zembla), commemorative of the celebrated voyage of Barends in 1695-97, is very popular and has often been reprinted, on one occasion in an illustrated edition. The poem is commemorated by the Dutch Days' Sea-Fight, commemorative of one of the desperate contests between the Dutch and English in the reign of Charles II., may be compared for spirit to his friend Loots's "Overwinning bij Chatham" (Victory at Chatham), a far more recent work. December of the same year contains a fierce ballad of ballads on subjects of Dutch history, among which his "Jan van Schaffelaar," "Keesau Hasselaar," &c., are conspicuous. His "Wapenkreet" (Call to Arms), written on occasion of Napoleon's return from Elba, is one of his best productions. The poem was translated from the German and English as well as the French, but often adapted the pieces he borrowed to Dutch subjects or history. An English reader would hardly suspect before reading it that the work was in any way connected with events which must be regarded as "Young Loochin," which has also been done into Dutch by Van Lennep, under the title of De Heer van Culemborg. Tollens's works, of which a new edition is now published, are of some extent: his shorter poems alone occupy about ten 8vo. volumes, not very closely printed.

TOLUOLE. [CHEMISTRY, 2.] TOUKE, THOMAS, one of the two sons of the Rev. William Touke, who was born in 1773. He published in 1838 A History of Prices and Prices of Production, and in 1837-1838, by a brief sketch of the State of the Corn-Trade in the last two Centuries, 2 vols. 8vo. The treatise comprised in these two volumes, though apparently an enlargement and continuation of one published about thirty years earlier, was found to be defective and unsatisfactory. Details on the High and Low Prices of the last Thirty Years, embarking, as it does, the same line of argument and establishing the same conclusions, is yet essentially different both in its arrangement and details, and is, in fact, with slight exceptions, entirely new. It forms the first two volumes of the valuable work now well known to political economists as the "History of Prices," perhaps the first really scientific attempt to elucidate by inferences legitimated by actual experience the complicated facts of this branch of political economy. The first two volumes were followed in 1840 by another volume in continuation of the two former, to which were added Remarks on the Corn Laws and on some of the Alterations proposed in our Banking System. The fourth volume was entitled A History of Prices and the State of the Circulation from 1839 to 1847 inclusive; with a General Review of the Currency Question, and Remarks on the Operation of the Act 7 & 8 Vict., c. 52., 8vo. 1849. Mr. Touke's works published in London in 1844 were: On the Bank-Charter of 1844, its Principles and Operation, with Suggestions for an Improved Administration of the Bank of England, 8vo. The last two volumes of his great work, the completion of a very valuable history of the State of the Circulation during the Nine Years 1848-1856, in Two Volumes, forming the Fifth and Sixth Volumes of the History of Prices from 1839 to the Present Time, by Thomas Touke, F.R.S., Corresponding Member of the Institute of France, and William Newmarch, 8vo. 1847. The 6th and 8th volumes, besides containing a continuation and completion of the work, arranged under the heads Prices of Corn, Prices of Produce other than Corn, and the State of the Circulation contains discussions on the connected topics of Railways and the Railway System, the origin and progress of the Free-Trade Movement, the State of Finance and Banking in France, and the New Discoveries of Gold. Mr. Touke died in London, Feb. 26, 1856, being then within a few days of his 79th year. His younger brother, William Touke, F.R.S., is still living.
The amnesty of 1823 restored him to Spain, but he was not permitted to reside in Madrid till after the death of King Ferdinand. In 1834, on the promulgation of the 'Estatuto Real,' by Queen Christina, on the recommendation of his friend, Martinez de la Rosa, he was named minister of finance. The measures he proposed for the state's economic growth, he said, were harmonious and could be carried out successfully for some time, and prevented his sharing the unpopularity of the chief, so that, when in 1835 Martinez de la Rosa was compelled to retire, Torero succeeded to his post as a strong support of the national council. Unfortunately for himself he admitted to his own post of minister of finance Mendizabal, who, with his dazzling schemes, soon threw him into the shade. Torero, who was now decidedly a 'Moderado,' grew more and more convinced that in Barcelona for the nation's welfare, a great body should be conformed to the constitution, the Barcelonan franchise, which he wished to repress by forceful means, but his colleague thwarted him, and the country was not with him. In September 1835 he was driven to resign, and Mendizabal succeeded as head of the cabinet. On a dissolution of the Cortes, Mendizabal was returned by the electors of other different places, and Torero and Martinez de la Rosa were left without a seat. The disgraceful revolution of La Granja followed, the constitution of 1812 was proclaimed, and Torero, now in great despair, it is reported, it expected to resume his historical studies in Paris and London, where he brought his history to a conclusion, at the time that in Madrid he was sentenced to forfeit all his honours and estates. In a few months, however, he was again allowed to reside in Madrid. In the subsequent years he vindicated his character against an accusation of corruption brought against him by General Secano. The revolution of Barcelona drove him to banishment yet another time. In 1841 it was the last. Torero, after a tour in Germany and Italy, went to Paris, and, on his return, it is said to Spain, when seized with a cerebral disease, which carried him off in a few days. He died at Paris on the 15th of September, 1845; but his remains were conveyed to his own city, and the church in Madrid, at Madrid, on August 19, 1846.

Torero's 'History of the Insurrection, War, and Revolution of Spain' ('Historia del Levantamiento, Guerra, y Revolucion de Espana'), is the great Spanish work on that interesting subject. That it is a model of Spanish composition is affirmed by the host critics of that country. Its merits as a narrative are more liable to question, for there appears a languor and general want of spirit in its details, which surprise the reader who is aware that its author was not only an eye-witness of many of the events he describes, but also an actor in some of them. The editor of the edition of 1849, published after the author's death, speaks of the 'carefulness and precision of the history, in which,' he remarks, 'the most insignificant French detachment is noted by him, specifying the names of the chief who commanded it.' A merit of more importance which Torero's history possesses is that of a calm judicial tone, which favourably contrasts with the arrogant impetuosity of the history of the same memorable conflict. On the whole, it can only be considered like Southey's 'History of the Peninsula War,' as a temporary substitute and a collection of materials for the great work on the subject, with which it may be hoped that some future historian will enrich the literature of his country. The 'Historia del Levantamiento' has been translated into French and German, and a Spanish edition of it was printed by Baudry of Paris in his collection of the Spanish classics. The history consists of fifteen large quarto volumes at Madrid in 1849, which is the author's death, with his additions and corrections.

TORQUAY, Devonshire, a small sea-port and watering-place on the coast of the English Channel, in the parish of Tor-Moham, or Tor-Michael of Haytor, is situated in 50° 28' N. lat., 3° 33' W. long., about 30 miles S. from Exeter, 194 miles W.S.W. from London by road, and 219 miles by the Great Western and South Devon railways. The population of the town of Torquay in 1821 was 2,805; in 1851, 4,005. It is the residence in the archdeaconry of Totnes and diocese of Exeter.

About fifty years ago Torquay consisted only of a few moon huts inhabited by fishermen. The mildness of the climate, and the favourable position and picturesque character of Torquay, induced many doctors and physicians to recommend it as a winter residence for invalids. The abundance of building stone, which is found in the vicinity, presents great facilities for building. The town has consequently very much increased. Torquay lies in a small sheltered recess at the north-eastern extremity of Torbay. On all sides landward it is inclosed by lofty hills, on the sides of which the houses are built. The town is lighted with gas and paved, but the supply of water is insufficient.

The pier, which is used also as a promenade, incloses a small but convenient tidal-harbours. The rise of tide at spring-tides is about 18 feet. The imports consist chiefly of American timber, coal and culm, Portland stone, corn, bricks, slates, and general goods: the exports include emery, eggs, mineral waters, and admixtures, which are exported to America.

TRACHEARIA, a subdivision of the great class Arachnida. It includes those forms of this class which carry off their respiration by means of ramifying tracheal tubes. They have two or four eyes. This division includes the walking forms of Mites, Ticks, Shepherd-Spiders, and Bes-Spiders. The following is a synopsis of the families of the sub-class from the 'Manual of Natural History,' by Means Adams, Balkie, and Barron:—

Order I.—Mononomosomatida.

Body without division, the head, trunk, and abdomen being united into a single mass; abdomen not annulated.

Sub-Order I.—Erranti.

Mouth with distinct mandibles; palpi always present; animal eye.

Family 1. Acaridae.—This includes the True Mites [Acaridae].

Family 2. Trombidae, Garden-Mites.—Palpi jointed, with a moveable appendage below the tip; feet formed for walking; facio-lateral-anterior; chelicere ending in a moveable claw.

Trombidium holosericeum is of a blood-red colour, and is very common in gardens during the spring.

Family 3. Gnapsidae, Spider-Mites.—Palpi filiform, in- curved; mouth with two discriminately chelicer; body depressed; skin soft or scaly; legs formed for walking; tarsi ungualicate. The Red Spider of our hothouses belongs to this family.

Family 4. Bexelidae, Wood-Mites.—Palpi fusiform, under the head, without hooks; mouth with discriminately chelicer; eyes not distinct; body hairy or scaly, produced and rostrate in front; legs formed for walking.

Sub-Order II.—Suctoria.

Mouth in form of a sucker, with or without palpi; as apparent mandibles; animal attached.

Family 5. Isopoda, Book-Scoops.—Palpi antenniform; mandibles ungualicate or cheliform; eyes distinct; sucker in form of an elongated bead; body with a escape; legs formed for walking.

Family 6. Hydrochidae, Water-Ticks.—Palpi with the last joint armed with points, the third and fourth joints larger than the others; body simple, oval, or rounded; eyes supero-anterior; legs elongated, formed for swimming; parasitic in the young state; aquatic.

The species are found in fresh waters. Hydrochaenus has the mouth composed of plates forming a projecting sucker.

Family 8. Lepidida, Harvest-Ticks.—Palpi short; sucker corredor; body depressed, corconvate, oval or rotundately; legs six, two being undeveloped.

Lentus antarcticus is very common in autumn up grass and other herbage. They crawl upon the human body, and insinuate themselves into the skin, producing great irritation. They are called Harvest Bugs.

Order II. Adelarthronosomatida.

Body divided into three or four distinct segments; abdomen distinct, annulated; mouth with complete oesophageal appendages, both terminal.

Family 1. Soljugidae, False Scorpions.—Mandibles in the form of large compressed claws, with a moveable finger palp large, in the form of, or of cheliferous arms, both being membraneous; oesophageal appendages carunculate.

Family 2. Cheliferae, Book-Scoops.—Mandibles short; didactyle at the end; palpi very large, annulated, with a pincer at the end; body ovate, depressed, narrow.
in front; legs of equal size, short, ending in two books.

Chelifer cancriformis is found in herbariums, old books, etc., where it feeds upon the minute insects which frequent such situations.

Family 3. Phalangiidae, Shepherd-Spiders.—Mandibles very conspicuous, composed of two or three pieces, free, ending in a didactyl pincer; palpil filiform, ending in a hook; body short, rounded; abdomen segmented; legs elongated; family comprises the well-known forms called Harvest-Men.

Sub-Class III. Aproschniata.

This sub-class includes the genera Nymphon and Pseu disclosures, which are the types of orders of Nymphonida, Phalangites, the Sea-Spiders, and Pseu disclosures, Parasitio Sea-Spiders. These are often referred to the class Crustacea.

TRACHYPHONUS. [Woodpockers.]

TRACHYPHONES, a genus of fishies belonging to the ribbon-shaped forms of Acanthoderigii. The body is elongated and compressed; dorsal fin extending the whole length of the back, a few of the anterior rays sometimes elongated; ventral fins fragile, if not worn or broken, rather long; no anal fin; caudal fin-rays rising almost vertically from the horizontal line of the vertebral column; a row of small spines along the lateral line.

T. Bogmarus, the Vaalnagel, or Deal Fish, is described by Dr. Fleming in the ‘Magazine of Natural History.’ He was the first British naturalist who has made known its occurrence in Scotland. The species found in the north of Europe differ from those of the Mediterranean. One specimen only has been recently caught alive at Sands in Urkney. It is thus described.—Length, three feet; body elongated, tapering, and considerably compressed, where it does not exceed a table-knife in thickness; breadth nearly five inches, tapering to the tail; colour silvery, with minute scales, the dorsal fin of an orange colour, and the iridescent greenish-blue with a golden shelf at the sides, the rays of unequal size; head four inches and a half long, compressed like the body, with a groove on the top; eyes one inch and a quarter in diameter: both jaws armed with small teeth. Various specimens, probably to the number of twelve or more, appear to have been obtained on the island of Sanda between 1817 and 1829. The Vaalnagel is rare in Iceland. It differs from the two species found in the Mediterranean, T. futex and T. iris, and also from T. Leuctrella.

TRADE, BOARD OF. The functions of this branch of the Privy Council have been of late years considerably extended, its duties being some of them of a ministerial, and others of a judicial character. It has the general supervision of the regulations of the Board of Trade; the carrying into execution the statutes in force relating to them. For that purpose it has to require and receive various kinds of returns as to trade and navigation, and originate and consider reports made to it by its inspectors and the Board of Trade, and to examine the returns of the officers of the Board of Trade, and to examine the reports of the Board of Trade. It may lay down rules as to the conduct of examinations, and as to the qualification of applicants for the posts of masters and mates of foreign-going as well as of home-trade passenger-ships.

It grants licences to persons to engage in or supply seamen or apprentices for merchant ships in the United Kingdom, adjudicates on claims for wages, and investigates cases of alleged incompetence and misconduct (17 & 18 Vict. c. 104). The Board of Trade exercises a supervision over railways and railway companies, not only with respect to their original formation, but also as to their subsequent working. Railways were first placed under this control by the statute 3 & 4 Vict. c. 97. A few years afterwards the powers of the Board in this respect were transferred to a Board of Commissioners of Railways; but in 1851 all the powers of this latter body have been devolved upon the Board of Trade (16 & 15 Vict. c. 64). Notices of application for Railway Acts, accompanied by plans, must be deposited with the Board, before any bills can be introduced into Parliament, and before a line can be opened for traffic, notice must be given to the Board. A Railway Bill is introduced on the report of an inspector, appointed by the Board for those and other general purposes. So, when accidents occur, notice must be given to the Board, and an inspector is generally sent to inquire into the circumstances, and on his report the Board may cause alterations to be made for the greater safety of the public.

The Board of Trade, through the medium of its registrar, is also charged with the registration of all Joint-Stock Companies (19 & 20 Vict. c. 44). By the statute giving a copyright in designs, their registration is effected by the Registrar of the Board of Trade (5 & 6 Vict. c. 100; 6 & 7 Vict. c. 65; 13 & 14 Vict. c. 104; 14 & 15 Vict. c. 8; 15 & 16 Vict. c. 29). The navigator of a ship whose imported articles are not all in large towns are also not at once immediate, the appointments connected with them being made by the president. The Board also controls the proceedings of the Commissioners for regulating the employment of coal-trippers and wharfingers, and the day labourers engaged in the port of London (6 & 7 Vict. c. 65; 9 & 10 Vict. c. xxvi; 14 & 15 Vict. c. xxviii). Lastly, a department of the Board of Trade is charged with the election and publication of tables, containing information with respect to the revenue, trade, commerce, wealth, population, and other statistics of the United Kingdom and its dependencies, as well as of foreign countries. The officers of another department collect and prepare the tables of the various classes of which forms, &c., before the submission of the corn-laws, regulated the amount of duty, and still render the charge in lieu of tithe under the Tithe Commutation Act (Blackst. ‘Comm.’ Mr. Kerr’s ed. v. p. 288).

TRADE, SHIPPING, AND CURRENCY. In the article GARDNER, the two last years were marked by the official and declared value of the imports and exports, with the number of ships and amount of tonnage engaged in the trade of the country, down to the year 1836. The value of imported merchandise was only shown in the official values of the materials and goods of our commerce has been constantly increasing, but without going through the details of each year, we shall give only summaries of 1854, 1855, and 1856, for which the materials are afforded in the three volumes of commodities enumerated in the Board of Trade in a highly improved form; and for 1857, which is only a preliminary return, and somewhat less complete.

Trade. The real value of the total imports into the United Kingdom in 1854 was 152,802,035; in 1855 it was 165,342,854, and in 1856 it was 172,444,151. The values of our imports are computed from the average prices fixed for the articles, which are chiefly entered by quantities at the Custom House. The value of the exports is obtained from the declared values set on the articles, except in the case of the foreign and colonial produce, of which the price is computed in the same way as with the imports. In 1854 the total value of exports amounted to 116,821,092, of which 97,164,726L. were for the produce or manufacture of the United Kingdom; and in 1856 the total value was 124,136,018, of which 95,926,946L. were for the produce or manufacture of the foreign and colonial produce. In 1855 the total value was 116,661,300L. of which 95,688,056l. were for the produce or manufacture of the United Kingdom; and in 1856 the total value was increased to 128,220,353, of which 115,826,946L. were for the produce and manufacture of foreign and colonial produce. The three years show less discrepancy than they were at 124,106,018L., 117,354,881L., and 191,097,763L.

Our largest imports in 1856 were from the United States of America; they amounted to 36,047,735; from Russia they were 11,661,025L. from France, 10,365,522L. from China and Hong Kong, 5,421,648L. from Turkey, including the Principalities, Syria, Egypt, and Tripoli, 8,660,900L. from Holland, 7,833,442L. from the Hanse Towns, 5,302,739L. from Prussia, 4,634,184L. from Spain, 3,965,894L. from Belgium, 2,936,794L. from Spanish West Indies, 3,354,399L. from China, 2,201,831L. from Portugal, 1,649,090L. from Sweden, 2,031,861L. from various states of South America, Central America, and Mexico, 9,788,365L. from the Western Coast of Africa, 9,142,254L. from the United States of America, 1,667,375L. (this commerce has doubled itself within four years). From the Two Sicilies, 1,605,628L. from Greece, 1,627,289L. The imports from other countries are each under a million. The total of imports from foreign countries was 129,071,687L., and the amount of importation was from the East Indies, 17,262,851L. the other principal amounts were,—the North American Colonies, including Newfoundland, 6,583,770L. the Australian Colonies, including New Zealand, 5,736,043L.
the West Indies, 4,167,084.; Mauritius, 4,247,067.; Cape of Good Hope, 1,502,828.; British Guiana, 1,418,349.; Cape Colony, 3,792,964.; and other colonies, 14,002,833. The exports from British possessions of the value of 43,026,561.

Of the exports, the total value taken by foreign countries in 1856, was 8,252,069. and by British possessions, 33,300,498. The United States (including Cuba, including the produce shipped from the Venezuela) took, in value, 21,918,105.; followed by the Hanse Towns, 10,134,813.; Turkey, including Syria and Egypt, 6,504,499.; France, 6,432,650.; Holland, 5,723,253.; Brazil, 4,084,537.; Spain, 1,714,483.; Belgium, 1,663,574.; Austria, 1,455,741.; China (exclusive of Hong Kong), 1,416,475.; Chili, 1,301,451.; Cuba, 1,317,062.; Two Sicilies, 1,202,183.; Sardinia, 1,143,684.; Sweden and Norway, 1,118,661.; Denmark (including Holstein, &c.), 1,084,140.; Portugal, 645,738.; and Russia, 298,957.; amounting together to less than a million sterling, and placed above a million. Of the British possessions receiving exports, the largest amount was by the East Indies (including Ceylon and Singapore), 11,607,439.; Australia (including New Zealand), 10,713,290.; North American Colonies (including Newfoundland), 4,010,282.; British West Indies (including Guiana), 1,873,397.; Cape of Good Hope and South Africa, 1,344,338.; these are the only places that exceed a million, but Gibraltar takes to the amount of 800,000.

The principal articles imported were—livestock (including horses) to the value of 1,488,691.; bacon and hams, 1,078,984.; butter, 2,353,182.; cheese, 1,094,260.; clocks and watches, 392,273.; coffee, 1,498,106.; copper and lead, 2,953,063.; honey, 1,814,303.; meal, 23,035,622.; cotton, raw and manufactured, 27,112,224.; flax and tow, 3,633,194.; fruit, including almonds, raisins, currents, &c., and oranges, spices, &c., 2,602,420.; guano, 2,136,431.; hemp, 1,694,578.; hides, 2,814,743.; indigo, 2,453,633.; olive-oil, 1,124,755.; palm-oil, 1,691,407.; salt and spermaceti-oil, 1,165,410.; oil-seed cake, 716,014.; rice, 2,031,647.; flax and linen, 3,196,654.; silk, raw and manufactured, 11,467,686.; almonds, 2,638,686.; spices, &c., 2,287,756.; wood, 2,000,000.; and many other kinds.

The rates declared were at New York, 20,816 vessels, 3,911,923 tons, in the year 1856, and 2,247,761 tons, in 1855.

Shipment.—In the year 1855 there were 22,871 British ships entered inwards, of which the burthen was 5,232,286 tons; in 1856 the number entered was 28,029, with a burthen of 6,390,710 tons, an increase in the year of 321 ships, and of 1,119,923 tons. In 1855 the number of foreign ships entered was 18,193, tonnage 3,880,641.; in 1856 the number of ships was 18,571, tonnage 4,162,029.; an increase in the year of only 28 ships, and of 281,388 tons; considerably less than a half of the British increase. Of the total amounts also in 1856 there were 7788 British ships with a tonnage of 1,304,453 entered in ballast; and 54 of the foreign ships, with a tonnage of 1,238,458.; an increase of only 6, of the tonnage 29,068. In 1855 the British ships cleared outwards with cargoes, of 5,036,926 tons burthen, and 2279 ships, of 612,014 tons burthen in ballast; in 1856 the numbers were 23,970 ships, of 5,885,681 tons burthen with cargoes, at 2,915 ships, of 671,185 tons burthen in ballast. The foreign vessels cleared out in 1855 were 16,167 ships, of 3,315,983 tons, with cargoes, and 3335 ships, of 577,553 tons burthen in ballast; and in 1856 there were 17,383 ships, of 777,447 tons burthen with cargoes, and 3361 ships, of 708,931 tons in ballast. The correspondence in the increase of the British trade is in its reports, notwithstanding the greater facilities offered by foreigners to the reuse of the original navigation laws. The returns include both steam and sailing vessels. Of the foreign vessels with cargoes, the greatest number in 1856 was from Norway, 2229 ships, of 488,744 tons burthen; the next highest number was from Denmark, 2053 ships, but of only 194,686 tons burthen, or less than 200,000. The British ships entered inwards in 1855 was 1210, the united tonnage being only 465,462; the size of the ships being suited to the low shores of Holland and the shallows of the North Sea: but, crossing the Atlantic, the United States received in 1856, 1439 ships, of 1,375,631, approximating to a thousand tons for each vessel. The burthen of the whole number of 15,231 British ships was 5,896,282 tons, an average of very nearly 280 tons each. The total number of registered British vessels, sailing and steam, was 36,012, of which the tonnage was 5,312,436, and the crews numbered 267,373 men, but this included the Channel Islands, and colonial possessions. In the British islands there were 6471 sailing vessels not exceeding 60 tons, and 12,027 above 60, and 329 steam vessels not exceeding 50 tons, and 743 above. In the Home Trade (which signifies the coasts of the United Kingdom, or to ports between the limits of the river Dee and the Firth of Forth, but does not include river steamers and river traffic), the burthen of vessels of 50, 60, and 74 tons burthen, with 33,570 men, and 317 steam vessels, at 67,616 tons burthen, and 4786 men. Partially in the Bay and partly in the Foreign Trade there were employed 595 sailing vessels, of 168,468 tons burthen, and 1583 men, and 226,969 tons burthen, and 965 men. In the Foreign Trade there were employed 3050 sailing vessels, of 2,942,674 tons burthen, and 110,716 men; 492 steam vessels, of 247,337 tons burthen, and 1178 men; and 2342 vessels, of 180,810 tons burthen, and 2475 men, entered in the United Kingdom, of which 921 were sailing vessels and of these 33 were of iron, of an aggregate tonnage of 187,000; and 229 steam vessels, of which 175 were of iron and with an aggregate tonnage of 67,573. In the Channel Islands, the value of vessels built and registered, of which the tonnage was 17,586, and there were 67 foreign-built vessels, tonnage 11,841.
registered at various parts of the United Kingdom. There were also 69 steamers and 6 sailing vessels built during the year for foreigners, the tonnage of which amounted to 34,601. There were 749 vessels wrecked during the year, 110 broken up, and 149 sold to foreigners, the tonnage of the whole, 249,459.

In the Coasting Trade in 1836 there were entered with cargoes (in ballast are omitted) 150,598 British vessels, 36,537 silver, 15,248,329, and 370 foreign vessels, tonnage 65,535. For the United Kingdom there entered 127,735 sailing vessels, and 24,752 coasting vessels, tonnage 24,735 steamers. The foreign sailing vessels entered numbered 288, the steamers 19; the number cleared was 315 sailing vessels, and 29 steamers.

In 1837 the notes of the Bank of England, including sailing vessels, and steamers, entered inwards with cargoes, was 19,691, the tonnage 6,418,090; the foreign vessels, 13,602, tonnage 3,314,090. Cleared outwards, there were 24,854 British vessels, tonnage 6,204,198; the foreign vessels 15,570, of which 6,506,292, The number of ships in ballast is not stated. Of the ships entered inwards Norway and Denmark still have the greatest number, Norway 2086, and Denmark 2311, while the United States sent only 1250 ships, nearly 200 less than in 1836, and the tonnage was 11,414,552. France sent 972 ships, 34,411,032 tons, although France only entered inwards 1122 ships, tonnage 90,038, she cleared out 4410 vessels, tonnage 473,859; Denmark cleared out 3141 ships, tonnage 316,625; Norway 1696 ships, tonnage 145,032; and the United States, 1295 vessels, tonnage 295,594. The number of ships employed in the Coasting Trade was 129,401 entered inwards, tonnage 12,979,068, of which 316 were foreign vessels, tonnage 48,619; cleared outwards, 144,355 vessels, tonnage 14,096,201, of which 321 were foreign vessels, tonnage 70,091.

Currency. At Michaelmas, 1837, the amount of Bank of England notes and post bills in circulation, was 17,086,610l.; the value of coin and bullion in hand was 3,826,000l. On October 17. At Michaelmas, 1837, the total amount of notes, other than Joint Stock Banks and Joint Stock Banks and Bank of England was 10,142,049l.; of which 3,701,996l. were of those Private Banks, and 3,440,653l. those of Joint Stock Banks. In the year gold to the value of 1,253,684l.. silver to that of 76,111l. and copper to that of 506,201l. The number of ships employed in the Coasting Trade was 129,401 entered inwards, tonnage 12,979,068, of which 316 were foreign vessels, tonnage 48,619; cleared outwards, 144,355 vessels, tonnage 14,096,201, of which 321 were foreign vessels, tonnage 70,091.

The value of gold and silver bullion exported in 1837 was 35,563,986l.; of which 15,061,600l. was in gold, and 15,505,384l. in silver. Of the gross sum 10,563,816l. in gold was struck into, and 1,035,328l. transferred to Egypt in transit to India and China. To no other country was so much as a million sent in both metals, except Brazil, to which was forwarded 938,014l. in gold, and 54,901l. in silver, a total of 1,012,913l. The Hansa Towns received 19,006l., and the Russian 7,465l. in silver; and the United States, 959,110l., all but 15,980l. in gold.

TRANSPORTATION [Savittude, Penal, &c.] TRAVNICK. [Botan.] TREE-FERN. [Cyathea, &c.] TRIELENODON. [Squalid.] TRIAKIS. [Squalid.] TRIGLOCHIS. [Squalid.] TRILLIUM. [Savittude.] The species are all native of warm climates, and yield the Rose-Wood of commerce.

TRITHEN, FREDERICK HENRY, a distinguished Sanoriit and Siavono scholar, was born in February 1820 in Switzerland when he was five years old. He removed to a few years old to Odessa, his father having accepted the situation of professor at a Russian college in that city. At Odessa he received an excellent education and had ample opportunities for making himself acquainted with the
modern languages, of which French, English, and German were as familiar to him as Russian. At the university of Edinburgh he pursued his studies more in the field of doctor of philosophy, he was distinguished for his knowledge of Greek, and he studied Sanscrit under Bopp. After passing some time in Poland, where he made himself master of Polish, he came to England, where, in 1841, he was set to work for a while as a translator. Dr. Tait, the present bishop of London. He then began to contribute articles, chiefly on subjects connected with Sanscrit literature, to the 'Penny Cyclopaedia' and the 'Bibliotheca Indica' of the Society for the Diffusion of Useful Knowledge.

In 1844 he was appointed one of the assistants in the Printed Book department in the British Museum, and was partly employed in cataloguing the Sanscrit and Arabic works. He added to the large stock which had then recently been added to the Museum library. In coming to the Museum he had indulged in expectations that his talents and acquirements would probably attract the notice of the Trustees with the effect of bringing encouragement and promotion, and he was deeply disappointed to find that such expectations were unfounded. He accepted in 1845 the post of private tutor in the family of Prince Chernichev, the Russian minister of war, and afterwards in 1846, Peterkin, left England after an absence of about two years, part of which he had spent at Constantinople and Cairo, and in 1848 published in London an edition of the 'Maha Vira Charita,' or History of Rama, a Sanscrit drama, by Bhavabhuti. He entered the service of the Trustees as the professor for the professorship of modern European languages in the Taylor Institution at Oxford, which was then on the point of being set in action. The professor, it was decided, was to be appointed at first for five years only, but with the capability of being re-elected; his post was to be one of influence and authority, the rest of the officials of the institution being placed under his directions, and his salary was to be 40l. a year. Dr. Trithen was elected to this post, and he agreed to come to Oxford and contrary to his own expectations, and entered upon his duties with a lecture "On the position occupied by the Slavonic dialects among the other languages of the Indo-European family," which he afterwards printed as an essay in the 'Proceedings of the Philosophical Society of London,' of which he had been a member since 1843. The career of usefulness and honour which now seemed to lie before him was suddenly cut short about the middle of 1850 by an accident which brought death. He was a masterly scholar, and his friends found it necessary to put him under restraint. It was reported at the time that the immediate cause of the disorder was, that a lady to whom he had paid his addresses had married a rival, but a tinge of eccentricity had on some previous occasions rendered him remarkable. His father came to England, and in 1851 removed him to Odesa, where he remained in a hopeless state till April 1854, when the city was under apprehensions of bombardment from the English. Trithen was then removed to a village at a few miles distance, where an unexpected change in his disorder took place, and he recovered his mental powers as suddenly as he had lost them, but this was only a lightening before death." After expressing a strong desire to return to England, it became evident that his bodily strength was failing, and he expired on the 27th of April 1854. He left behind him no adequate monument of the extent of the powers which his friends knew him to possess, his name is to be found in the biographical literature in the Cyclopaedia and Dictionary of National Biography, and so is his character, and his scholarship was not only accurate but remarkably. The power which he possessed of conversing with ease in more than one of the Teutonic, the Romance, and Slavonic languages, which qualified him in an eminent degree for the professorship to which he was chosen.

TRUDERGEB, Tailorworts, a small natural order of Polycarpia belonging to Lindley's class Dicyogamae. They have the dityogenetic stamens, unisexual, compound, and numerous 1-seeded carpels. There are only two genera, Trityrus and Peltophyllum. The species of these plants were discovered by Mr. Miers and Mr. Gardner in the woods of the Island of Madagascar in the right place of the sea. Their relations are with Sinilla, Menispermacae, and Trillaeae. TRUCTITE. [MINERALOGY, s. 1.]

TROWBRIDGE. [Wiltsnter.]

TRUMFET-FISH. [Ctenarchus.]

TRURO, THOMAS WILDE, FIRST LORD, the son of a respectable solicitor in Warwick-square, London, and Saffron Walden, Essex, was born in 1782, and received his early education at his father's solicitor's in Warwick-square. He was articled as his father's clerk and was later made an attorney in 1806, practised for some years as partner in the firm of Wilde and Knight, in Castle-street, Falcon-square. In 1817 he was called to the bar, and went the Western Circuit, and attended the House of Commons, in which he carved himself as an advocate, and became leader of his circuit. In 1824 he was made a serjeant-at-law, and three years later a king's serjeant, and a vast ascension of business was the consequence. Under Lords Denman and Brodie, who were the leading advocates of the time, he was accustomed to use the House of Commons, where he was probably the most popular member, and certainly the most respected. He was one of the most able advocates of the time, and was constantly in the court of appeal. His practice was very extensive, both at the bar and in the House of Commons, and he was frequently called upon to engage in the defence of the late Duke of Newcastle, and though thrown out in December 1832, he regained his seat in January 1833, and retained it, as colleague with Mr. W. E. Gladstone, until 1841, when he was elected for Worcester. In 1839 he succeeded Sir R. M. Bole, now Lord Crossworth, as attorney-general of the Duchy of Lancaster, and was returned for Newmarket in 1846, and was re-elected in 1841. In 1846, on the return of the Liberal party to power under Lord John Russell, Sir Thomas Wilde was again nominated attorney-general, but within a week afterwards was raised to the bench as chief-justice of the Common Pleas. He returned for the second time in 1850 the great seal, and was at the same time elevated to the peerage as Lord Truro. He resigned the chancellorship on the retirement of his party from office in February 1852. The most memorable causes in which he was professionally engaged before his elevation to the judicial bench were the trial of Queen Caroline, alluded to above, and the trial of the late Mr. O'Connell in 1844, to whom he gave his services without fee or retainers to obtain a reversal of the decision of the law courts and of the COMPANIES by which he was permanently connected with the great oase of Stockdale v. Hansard, which involved the constitutional question as to whether the House of Commons had the right of publishing its reports without rendering its officers thereby liable to before his elevation to the judicial bench were the trial of Queen Caroline, alluded to above, and the trial of the late Mr. O'Connell in 1844, to whom he gave his services without fee or retainers to obtain a reversal of the decision of the law courts and of the COMPANIES by which he was permanently connected with the great oase of Stockdale v. Hansard, which involved the constitutional question as to whether the House of Commons had the right of publishing its reports without rendering its officers thereby liable to...
legal decisions were too frequently based, and to insure that they shall henceforth be given according to their own respective merits, "according to the very right and justice of each case," as more fully explained in Finch's "Summary of the Common Law Procedure Act," 1834.

Lord Turvo was twice married: his second wife, who survives him, was Mademoiselle Augusta Émide d'Este, daughter of H.H. the late Duke of Sussex. He died at his residence of Lord Holland's, on the 11th of November 1855, and was buried by the side of the late Sir Augustus d'Este, in the Old Minster Church at Ramsgate.

TRUSTEES. Owing to the inadequacy of the existing law to meet the case of the defalcations and frauds of trustees, bankers, or others, it becomes important to arrange with the care and management of the property of others, a statute was passed in 1857 (20 & 21 Vict. c. 54) whereby the following offences were made a misdemeanour punishable with penal servitude for three years, or imprisonment, not exceeding two years, with or without hard labour:—

1. The appropriation or disposal, with intent to defraud, by a trustee of any property held for the benefit of some other person, or for any public or charitable purpose.

2. A banker, merchant, broker, attorney, or agent, selling, pledging, or in any manner appropriating, with intent to defraud, the property of any other person entrusted to him for safe custody.

3. Any person entrusted with a power of attorney for the sale or transfer of any property, fraudulently selling or transferring it.

4. A director, member, or public officer of any body corporate or public company, fraudulently taking or applying, for his own use, any money or property belonging to it, or any money or property belonging to it, or any money or property belonging to it, or any material omission in any book of account of any other document.

5. Any director, public officer, or manager of any body corporate or public company, receiving or possessing himself of any of its money or other property, otherwise than in payment of a just debt or demand, and with intent to defraud, or making or taking any false entries or transferring it, or any other person in trust for the public, or for the use of any charity, any money or property belonging to it, or any money or property belonging to it, or any material omission in any book of account of any other document.

6. Any director, manager, public officer, or member of any body corporate or public company, or any person in trust, or making or taking any false entries or transferring it, or any other person in trust for the public, or for the use of any charity, any money or property belonging to it, or any money or property belonging to it, or any material omission in any book of account of any other document.

7. Any director, manager, or public officer of any body corporate or public company, who makes, circulates, or publishes, or concurs in making, circulating, or publishing any written statement or account which he knows to be false in any material particular, with intent to deceive or defraud any person, or the holder, or the owner, of any money or property belonging to it, or any money or property belonging to it, or any material omission in any book of account of any other document.

8. Any person knowingly receiving any chattel, money, or valuable security, which has been fraudulently disposed of, under any of the above provisions.

The statute further enacts that a bailee of any property fraudulently taking or converting it to his own use, or to the use of any other person than the owner thereof, although he shall not break will or otherwise determine the bailment, shall be guilty of larceny.

TRUSTS, CHARITABLE. The sovereign, as parens patriae, has the general superintendence of all charities: which he exercises by the keeper of his conscience, the Chancellor; and, therefore, whenever it is necessary, the Attorney-General files ex officio an information in the Court of Chancery to have the charity properly established.

Until the passing of Sir Samuel Romilly's Act, in 1812, this was the only ordinary mode of redressing a breach of trust by the trustees of a charity. Sir Samuel Romilly's Act introduced a more summary and efficient remedy for such breaches of trust. For this purpose any two or more persons were enabled, with the permission of the Attorney or Solicitor-General, or the Attorney-General in Camera, praying such relief as the nature of the law might require, to apply to the court, that such petition should be heard in a summary way upon affidavit, or such other evidence as should be produced, the order thus made to be final, unless appealed against to the House of Lords within two years. This Act led to the appointment of Commissioners, who were to report upon cases of neglect, abuse, or breach of trust; and the reports of this body, which now extend to 38 volumes, form a valuable collection of information upon the subject of existing charities. Additional powers were given by the Acts 3 & 4 Vict. c. 77 to the Court of Chancery with respect to grammar schools, but the latest and most important piece of legislation on this subject is the "Charitable Trusts Act," 1876, passed to secure the due administration of charitable trusts, and in certain cases a more beneficial application of charitable funds than that previously in operation. For these purposes a permanent board of commissioners is constituted, called "The Charity Commissioners for England and Wales." It has power to inquire into all or any charities, their nature, objects, and administration, and the condition of the estates and funds belonging to them. This board is empowered to require all trustees of charities to render in writing to the board or its inspectors, accounts, explanations, and answers, to any inquiries, and to produce any documents in their custody.

When the income of any charity exceeds 30l., and in the case of a London charity even when the income is below 30l., the Master of the Rolls and the Vice-Chancellors are to entertain any suit which may be brought for its administration. In the administration of charities where the income does not exceed 30l., jurisdiction is given to the county court or the court of bankruptcy of the district where the charity is situated. The district court or the court of bankruptcy or county court may, however, be brought by the commissioners before a judge of the Court of Chancery, for reconsideration. [COURT OF COUNTIES, S. 2.] Application to be made by the Attorney-General, by any one or more of the trustees or managers of the charity, by any one interested in it, or by any two or more inhabitants of the place where it is administered; and as the courts are prohibited from entertaining any legal proceedings (except with the concurrence of the Attorney-General) unless upon the certificate of the board, the first proceeding is, in almost all cases, to communicate with that body and obtain its sanction and advice. The powers of the Attorney-General in which it performs the function of extracting information on the subject of charities, enable it to afford the most efficient assistance to individual informants. The statute does not extend to Scotland or Ireland; and from its operation are excepted the Universities of Oxford and Cambridge, and certain other institutions. A report of the proceedings of the Commissioners must be annually laid before Parliament. [Blackst. 'Comm.,' Mr. Kerr's edition, v. iii., p. 483.]

TRYPHILINE. [MINERALOGY, S. 1.]

TURKEY. The profits of Turkey are divided into Eyalets or general governments, each administered by a pasha, who is generally styled Vali, or vice-reg. The Eyalets are divided into Livas, governed by Kaimakans, or lieutenant-governors. The Livas are subdivided into Cazas, or districts, and these again into Nahijes, or communes, containing villages and hamlets.

Turkey in Europe contains 15 Eyalets, divided into 43 Livas, and 376 Cazas. Turkey in Asia is divided into 18 Eyalets, 78 Livas, and 828 Cazas; Turkey in Africa into 3 Eyalets, 17 Livas, and 86 Cazas. The following table gives the names of the Eyalets, with the chief town of each, extracted from M. Uboin's recent work upon Turkey:—

The total area of the Ottoman empire, including the tributary provinces, is estimated at 1,220,000 square miles, of which about 360,000 are in Europe, 560,000 in Asia, and 300,000 are in Africa.

With regard to the administrative division of the empire, it must be observed that neither the eyalets nor the sanjaks, or livas, have such invariable limits as provinces in Europe usually have; and with regard to the population, it is pleasant to dwell on the numerous improvements the Ottoman empire has undergone, but almost independent states of Servia, Moldavia, Wallachia, Egypt, Tripoli, and Tunis, the inhabitants subject to the Porte do not much exceed 20 millions.

Abdul-Medjid, son of Mahommed II., ascended the throne of Osman in 1839, in his 18th year. He immediately proceeded to Nezir, the treachery of the Cephan pashas, who deserted to Mehemet Ali with the whole of the Turkish fleet, and the advance of the victorious Ibrahim, seemed to foreshadow the immediate dissolution of the Turkish empire. This disaster was prevented however by the treaty of London (July 16, 1846), in fulfilment of which an Austro-English fleet bombarded and took Acre, Sion, and several other towns on the coast of Syria, which Ibrahim Pasha was obliged to evacuate. Negotiations for peace soon followed, which terminated in the restoration of the Porte to the coast, and the recognition of Mehemet Ali as hereditary pasha of Egypt and its dependencies, upon payment of an annual tribute.

The Swiss, who had revolted from their allegiance to the Osmanli Porte in 1830, were defeated by the Russians, and Varna, the last stronghold of the rebellion, was taken in 1841. Turkey was thus left in undisputed possession of the Black Sea and the islands of the Dardanelles, which had been ceded by a firman of 1769. The Turks were now, however, reduced to the defensive, and their power was sapped by internal dissensions and foreign attacks.

The numbers of the different races of which the population is composed are given as follows:

victories of Inkerman and Balaklava; and kept the eyes of the world fixed upon the spot where the whole interest of the war was now concentrated throughout the entire spring and summer of 1855, electric agency flashing to all parts of Europe tidings of losses and sufferings often, of defeats and successes, the reports of which, which was the victory of Tokharnya, August 16, in which the Sardinians, then numbered among the allies, fought with great skill and courage; until last, at last, a long bombardment, the French captured the Malakoff fortress on the 27th of July; all the同时 TURNER, JOSEPH MALLORD WILLIAM, was born at No. 26, Maidew-jane, Covent Garden, where his father carried on business as a hair dresser. The year, as well as the name of his family, was differentially given: all that is certainly known respecting either is entered on the register of the parish church of St. Paul's, Covent Garden, as having taken place on the 14th of May, 1775; and it is most probable that his baptism followed pretty close upon his birth. Of his boyhood and youth little is told. His father, a tradesman in a small way, did not attempt to make his son a scholar, and the great painter never advanced far beyond the rudiments of an ordinary English education. Of his primary training in art, or what little his father may have taught him by conference, we have no precise information. Probably his own strong inquisition first stimulated him to overcome the initial difficulties of the study of drawing, and some casual occurrence or association may have furthered his education. It does not appear that the elder Turner thwarted his son's bent, although, perhaps, from poverty, perhaps from indifferenced, he did not procure him the instruction which might have smoothed his early path.

Gilpin, the self-made painter. It is said in a brief notice of him published in 1805—when, though only in his thirtieth year, he was already recognised as the first of living landscape painters—"Turner may be considered as a striking instance of how much may be gained by industry, and how little, compared with the assistance of a master. The way he acquired his professional powers was by borrowing when he could a drawing or picture to copy; or by making a sketch of any one in the Exhibition early in the morning, and finishing it up at home. By such practices, and by much perseverance, he has overcome all the difficulties of the art."

(Dayes' "Professional Sketches of Modern Artists," Works, p. 352.)

This passage was written by one eminent in his day as an inimitable copy of what was then a fair imitation of his friend of Girtin, Turner's earliest and closest artistic associate, and it coincides with what other authorities, both written and traditioanary, have always related of his career. But he was certainly very young when he had opened to the academicians the gates of his rooms, and of his having been admitted as a student in the Royal Academy in 1789, when consequently he was only fourteen years old. It is hardly probable, however, that he received much direct instruction in the Academy school; but that he followed their prescribed course. If he studied in the antique, or later in the life-school, he certainly never acquired mastery over the human form, and no instruction was given the student in landscape drawing or painting. Still it is not likely that a young enthusiast, as he certainly was, would attend the schools and form acquaintance with professors and students, without acquiring from them much technical information, even if he received no systematic instruction. But his best education, he was accustomed to say, was "the first day with Dr. Malton," and as he was a warm-hearted patron of young artists, had an excellent collection of water-colour drawings and engravings at his residence in the Adelphi, and he not only gave his two favourite protegés, but also, free access to his treasures, with permission to copy them, but directed their studies, and encouraged them to make coloured sketches of the scenery around London, which he readily purchased at prices satisfactory to the modest students. In those sketch- ings, with their lithograph copies, which he showed them, and they formed for themselves a style of water-colour painting very different from that of any of their predecessors—unless indeed it be Cozens, a man of some genius and a friend of Dr. Malton, from whose drawings and conversations he was probably learned by the two young painters. Girtin was Turner's senior by a year or two, and as he was the more regularly educated artist, it is not unlikely that he was to some extent his companion's tutor; certain it is that their drawings were very similar in style—the chief difference being that Turner made out his details more carefully—and some have fancied that had Girtin lived he would have been as great a painter as his friend. He gave early promise of success, however, for he died (Nov. 6, 1802) up to the early age of twenty-seven. Turner, with more self-control and perseverance, laboured steadily on, and rose in good time to the undisputed supremacy in his branch of art.

Ten years before he entered the Academy as a student, in 1787, when only twelve years of age (supposing his baptismal year was the year of his birth), Turner made his bow to the public as an exhibitor at the Royal Academy (under the name of 'the son of Turner') of two drawings, 'Dover Castle' and 'Wanstead House'; the first being exhibited in 1790, the year following his admission as a student, when he sent a 'View of the Archbishop's Palace, Lambeth.' From this time till his death—a period of sixty-years—he regularly contributed to every exhibition of the Royal Academy, with the exception of the years 1821, 1824, and 1848, sending in all 289 pictures, a very large proportion of them being paintings of considerable magnitude. But these alone would give a very inadequate notion of his labours and labours. He also sent a number of drawings every year, and was the most remarkable exhibitor in the Royal Academy. He also sent to the British Institution some twenty oil paintings which had not been exhibited at the Academy, and painted a large number, and some of them his chief works, which, with all other, he bequeathed to the nation, being hundreds of water-colour drawings and sketches for engraving. For some ten or twelve years he painted chiefly, if not exclusively, in water-colours, his pictures—with the exception of two or three fancy subjects, such as 'The Battle of the Nile,' his 'Fourth of May,' his 'Dreadnought,' 'Prodigality,' 'The Infancy of Christ,' 'The Holy Family,' another (1807) 'A Country blacksmith disputing upon the price charged to the Butcher for shoeing his Pony,' another (1808) 'The Unpaid Bill, or the Dentist reproving his Son's Prodigality,' and another (1809) 'The Gazetteer's Petition;' but even from these strange whims he seemed to gather new strength. At this time however he appears to have studied with most steadfastness the stormy ocean, and never yet has the sea in its wildest fury been represented on canvas with such wonderful power. In his '1805' and '1806,' and 'The Limehouse Packet,' the fortresses of Malakoff and Sebastopol, the battles of Balaklava and Sebastopol, the loss, and the strength of the British fleet, are represented not only in their true proportions, but also in the true position of the ships, and the distant and near view is taken of their performances, which no other artist has been able to do. The 'Gloomy Morning,' 'The Fairy Bower,' and 'The Fort at Anacreon,' are still among the poetic treatment of views of places, such as his 'Edinburgh from Calton Hill,' '404; Fall of the Rhine at Schaaffhausen,' '1805,' and 'Sun Rising through Vapours,' 1806, not only enabled them to hold their place, but remain among the very choice subjects in the gallery of the British Institution. He was also a great admirer with the connoisseurs his 'Narcissus and Echo,' 1814, 'Mercury and Mars,' and 'Apollo and Python,' 1811, his 'Dido and Aeneas,' 'Aphelis,' and a long list of other mythological themes. He had his own most singular way of depicting these. He went to the seaside with as many talents and riches as he did not want to be in truth the least poetical of his works, and infinitely inferior to his other and more
purely imaginative productions of this period, 'Snow-storm—Hannah crossing the Alps,' and the like, in which he almost for the first time portrayed with some approach to the vastness and splendor of nature the fierce encounter of the elements, the splendor of the rarer phenomena of the atmosphere, and the beauty and glory of the mountains.

In 1807 Turner was elected professor in perspective to the Royal Academy, and for several years he continued to give courses of lectures to the students, in which he spoke of his own compositions by the great landscape painters of earlier times, of their principles of effect and of colour, and compared them though sparingly with the teaching of nature; but the lectures were never printed, and we know no fragment of them. Report has always spoken of them however as ill-arranged and ill-delivered, confused in style, and obscure in illustration. They never succeeded in securing the attention of the students, and for many years before he resigned his professorship he had ceased to deliver any lectures.

An important circumstance in the earlier career of Turner was the publication of his 'Liber Studiorum,' which was commenced in 1808. This now famous work was undertaken in rivalry of the book of sketches known as the 'Liber Veritatis' of Claude, and the possession of the Duke of Devonshire, of which a series of fao-simile aqua-tinta engravings was made by Earlom and others. Turner's views were engraved in a similar style, some of them by Turner himself, and as many as possible of the principal forms of landscape composition, and displayed a fertility of resource and an intimate observance of nature such as the publication of no previous landscape painter had approached. The work has long been extremely rare, and only a few specimens of high expense and two re-publications of it have been announced. From this time to his death Turner remained the most in request with publishers and engravers of any English landscape-painter, both for the landscape illustration of books and for series of engravings; and even where his eccentricities of colour, as they are called, repel, his engraved designs are with few exceptions received with unmitigated delight. Among the most famous of these engraved works may be mentioned the 'Scenery of the Southern Coast—England and Wales,' 'Rivers of England,' 'Rivers of France,' Rogers's 'Italy' and 'Poems,' of all his vignette engravings the most exquisite, the poems of Byron, Scott, &c. From his paintings likewise some very noble line-engravings of large size have been made by Fye, Wollaston, Milier, Prior, &c.; while Turner's grand engraving of 'The Shipwreck' is one of the richest specimens of mezzotinto. We cannot in a sketch like this trace the progress of the pupil and the man, the important events recorded of his life—the production of his chief pictures. He made three visits to Italy in 1819, 1820, and 1840, and after each his style underwent a remarkable change. The usual division of his style is, as a whole, the least convenient. Neither visits, paintings, nor periods, accordingly, have been of much service. The first visit to Italy was that which was the most important one, does not however exactly correspond with the first visits. Turner's career, it is said, comprises three distinct periods; the first reaches to about his twenty-seventh year, when he was elected into the Academy, and during which he was chiefly noticeable as a water-colour painter diligently occupied in drawing from nature, and at the same time forming for himself a style, by carefully studying (and imitating) the methods of his English predecessors, Wilson, Liotterbourgh, and Stothard, and a degree, Guisborough, the influence of whose works is very apparent in his early efforts: the second period ranges from 1802 to 1830, in which he is seen at first a follower of Claude, and, in a less degree, of Gaspar Poussin, but rapidly disseminating himself from the trammels of every kind of pugnace to great names and striking out a style of landscape-painting entirely original and wholly unirrilluated for brilliancy of colour and effect: while the third period, dating from his second visit to Italy, in 1829, is one in which everything else was sacrificed in the interest of this, and in his whole style of light and colour—to make (in the strange language of his own 'MS. Fallacies of Hope')

the sun
Enahle earth's humid bubbles, and, embers of light,
Refract her forms each in prismatic guise.

But while such a division is convenient it must not be regarded as anything more. Like every great artist, his conceptions were always advancing and expanding, and in each period were painted pictures that would seem justly to belong to another. At which period he painted best it is difficult to say, and judges of art pronounce widely different opinions. It is quite certain that to some ten or twelve years before his death, his knowledge of the phenomena of light and colour, and the means of expressing them with that brooding, inexpressible effect, was beginning to expand, even when his hand failed to express faithfully his intentions, or his impatience prevented him setting them forth with due elaboration. Any one who has carefully studied Turner's works chronologically, and who has seen him at work, will feel that he has never been as an artist in the full sense of the word; for the same works that have been as evidently as it has been swiftly progressive, and in different stages of the struggle, sometimes one order of truth, sometimes another, has been aimed at or omitted. . . .

As he advanced, the previous knowledge of his ambition was absorbed in what succeeded, or abandoned only if incompatible, and never abandoned without a gain; and his latest works present the sum and perfection of his accumulated knowledge, delivered with the impatience and passion of one who feels too much to allow any longer to have too little to say to it in pause for expression, or to ponder over his syllables." ('Modern Painters,' i. 401.)

It would be easy to refer to examples illustrative of Turner's different periods, but so large a number of his works have been sold and dispersed amongst private property, and through the care of Mr. Wornum have been so well arranged, dated, and catalogued, and rendered so easy of reference, that a special mention of any is needless. A cursory examination (with attention to the dates) of that collection will suffice to show the extreme diversity of his output. A glance through the public galleries, will sufficiently illustrate what has been said of the progressive and, as it were, tentative character of his mind; and a studious consideration will convince the visitor that amongst all his works Turner's wildest aberrations from the sobriety of nature, there is a foundation of truth for the idea he has endeavoured to work out, and that his failures, while they arise sometimes from wildness, arise more often from his attempting to represent unusual phenomena by materials utterly inappropriate for the purpose. Turner in fact never seems to have understood the limits of his art, and in seeking to accomplish what is impossible with such means as he possessed, and with such necessarily imperfect skill, he became extravagant and bizarre. Although eccentricities of colour and indefiniteness of form were at all times charged upon his paintings, the extreme development of this fault is chiefly urged against the works executed during the last twenty years, usually from 1830 to 1840. This is the period of unfailing suggestiveness, to an artistic eye, in every one of them, it is upon these works that censure will eventually rest. Yet it is remarkable that to this period belongs the work in which, by general consent, his unrivalled powers are most clearly displayed. We have reached the fullest development, his 'Childo Harold, or Modern Italy,' (now at Marlborough House) which was painted in 1822; and to this period also belong some of his most poetical efforts, including 'The Fighting Temeraire lugged to her last Berth' (1839), and the 'Slaves throwing overboard the dead and dying—Typhon coming on' (1840).

Turner died on the 19th of December, 1851, in humble lodgings, which he had taken in an assumed name, by the name of Mr. Coke. He was then living near the 'Trinity' in the crypt of St. Paul's Cathedral by the side of Reynolds, Wilkie, Fuseli, and others of our eminent painters. Turner was a man of unsocial and reserved manners, and many gossiping stories are related of his eccentricities and love of money: but they bear on their face a coloured and exaggerated character. It is certain that he had hoarded his money for no selfish purpose. For many years he had refused to sell of his best pictures, and when any pictures or drawings of his were sold, he never gave any account of the sale, if he possible purchased them. On his death it was found that he had by his will bequeathed to the nation all the pictures and drawings then collected in his residence, and the funds raised by the sale of some of his pictures to the Trust, which was to be used to build a suitable gallery for erected for them within ten years; and his funded property to found an asylum at Twickenham for decayed artists. Unfortunately the will was unskilfully drawn, and a suit in chancery ensued, but it was compre-
mised by the engravings and one other property being transferred to the next of kin, which disputed the will, while the paintings and drawings were held by the nation. The oil paintings, one hundred in number, include many of his finest works as well as examples of his pen from the outset to the termination of his career; they are for the present exhibited at Marlborough House. The finished drawings, which number several hundreds, and the sketches, which amount to some thousands, have been (or are being) exhibited by Mr. Ruskin, who volunteered his services to the government; and a choice selection of them is now hung on screens at Marlborough-House. Among those now exhibited are many admirable drawings in colours, and numerous sketches and drawings of scenes on the Rivers, &c., of which are of an exquisite beauty and brilliancy of effect, probably unequalled among drawings of that character. The nation also possesses in the collections presented by Mr. Vernon and Mr. Stephens and several other choice examples of Turner's pencil.

There is no need to add anything to what has been said respecting the rank which Turner holds among the landscape painters either of his own or an earlier time. But as his style was a more perfect composition of character, perhaps in part owing to the indiscernible eulogy which has of late years been heaped upon him—and as it is sometimes said that, if he were the great painter so strongly admired by his contemporaries, and writers on art would not be slow to acknowledge his superiority—it may be well to quote the calm judgment of a German writer whose authority is admitted, and whose opinion is the result of a repeated consideration of his works. Dr. Wegelin says: "His powers are so great, that his art seems to be an expression of something beyond his own province, perhaps with such versatility of talent. His historical landscapes exhibit the most exquisite feeling for beauty of lines and effect of lighting: at the same time he has the power of making them express the most varied moods of nature—a lofty grandeur, a deep and solemn atmospheric, a sunny cheerfulness and peace, or an up roar of all the elements. Buildings he also treats with peculiar felicity; while the sea in its most varied aspect, is equally subservient to his magic brush. His views of the past have yet sustained them; and he inspire the spectator with pensive feelings such as no other painter ever excelled in the same degree, and which is principally attributable to the preceding picturesqueness of the point of view chosen, and to the beauty of the lighting. Finally, he treats the most common little subjects, such as a group of trees, a meadow, a shaded stream, with such art as to impart to them the most picturesque charm. I should, therefore, not hesitate to recognise Turner as the greatest landscape-painter of all times, but for his deficiency in one instrument of art, and in the application of the technical basis."—("Treasures of Art in Great Britain," 1854, vol. i., p. 383-4.)

TURNER, SHARON, was born in London on September 28, 1820. Her father was Mr. Theodore Wilkins, who was kept by the rector of St. James's, Clerkenwell, and at the age of fifteen he was articled to an attorney. On the death of his master, before his clerkship had expired, he succeeded him in his business. Even during his clerkship he had felt the promptings of a literary taste, and had occupied his leisure by studious reading and composition. While in business for himself he began to collect materials for his "History of the Anglo-Saxons," of which the first volume was published in 1850, and the third in 1853. It is the only work which has been written by a woman on the subject, and has been generally sustained now that the study of Saxon literature has been more appreciated, and the authenticity of his materials more vindicated, and a permanent place in the historical literature of the country, and, encouraged by his success, he continued his history from the Norman conquest to the death of Elizabeth, published in 1859. This portion, though distinguished by a large amount of industry, and the discovery in consequence of a few hitherto unknown facts, was not equal to the previous portion. Where the field was less new he had no advantage over previous writers; his views had little originality, and his treatment of his subject had no superior merit. In 1829, after suffering from illness, he removed to Winchester, where he prepared and published in 1832 the first volume of his "Sacred History of the World," as displayed in the Creation, and subsequent events to the Deluge. Mr. Turner's object was to be philosophically considered in a series of Letters to a Son." Two other volumes completed it, the object being, from temporal history, to establish the principle of minute providential agency or supervision. In 1849 the death of his wife occasioned him much distress, and increased his desire to return to London, where, in his old residence in Red Lion-square, he died on February 13, 1847. Besides the works above-mentioned, he published a volume of essays and poems under the title of "Sacred Meditations," by a Layman, a "Prolusion on the Greatness of Britain, and other Subjects;" "Richard III., a Poem;" and he contributed two or three articles to the "Quarterly Review." Some letters which he addressed to the Royal Society of Literature, of which he was an associate, on his own work and productions of the classical languages of the world, have been added to the last edition of his "Anglo-Saxons."

TURNER, THOMAS HUDSON, was born in London in 1816. His father was a painter in the employment of Mr. Bulmer in Pall-Mall, and on his decease his family was assisted by Mr. W. Nicol, the nephew and successor of Mr. Bulmer, who placed young Turner at school at Cheltenham, where he early distinguished himself by his love for humanitarian research, and formed a friendship with the two sons of the late Allan Cunningham. With the younger, Peter, his friendship continued until his death. In 1831 he was taken into the printing-office of Mr. W. Nicol to learn the business. While here he employed all his leisure in pursuing his own studies, and, on seeing an advertisement for a young man at the Record Office in the Tower who could read and translate records, he applied for and obtained the situation.

He devoted himself with great diligence to the study of the records, and his knowledge increased as he projected many historical works, but his labours in acquiring constantly fresh information prevented his carrying his many plans into execution. From this employment he was taken by Mr. Tyrrell, the Remembrancer of the City of London, to assist him in collecting materials for a history of London, at which he most assiduously laboured, but the information thus collected remains yet in manuscript. When this was completed he edited with remarkable care a small volume of the "Gleanings of London," 1848, which fixed a valuable introduction; the work being presented to the Roxburghe Club by Mr. Beriah Botfield. After the publication of this volume he was made secretary to the Proceedings of the "Archaeological Journal," published between 1846 and 1851. In 1852 his readiness in imparting information respecting antiquities was remarkable; he wrote some valuable papers for the "Journal" of the Society, and communicated several records to the Society of Antiquaries at Newcastle, which are printed in the "Archaeologia Zilliana." On his retirement from this office, he continued his studies, but commenced his work, "Some Account of Domestic Architecture in England, from the Conquest to the End of the Thirteenth Century, with numerous Illustrations," which was published in 1851. His work, "A Survey of the Conjectural Antiquities of England," published between 1846 and 1851, formed the groundwork of his fame. The papers only amount to five, and one of them is on the dining-customs of the Middle Ages, a subject similar to that of his book. The "Journal of Archaeology" is noticeable for the exactitude and wide extent of his knowledge, and is a valuable contribution for the study of English antiquities. It does not confine itself to the mere building, but includes a large amount of subsidiary information, in connexion with the study of the country records, and comprehends an account of the furniture; the implements used in the processes of cooking, brewing, baking, &c.; the state of agriculture at the time; with the description of the condition of the London household economy, such as glass, linen, cutlery, &c. Mr. Turner's severe and constant application to his studies had for many years greatly impaired his health, and on June 17, 1852, he died, having produced far less than from his
great accomplishments could have been wished and might have been expected. His vast store of knowledge was freely scattered in conversation; he had constant applications for information, and few were sent away unsatisfied; but his ardour for accumulation prevented his application to composition, so that of his many projected works the one above-named was the only one he announced, and that was in a manner but a fragment: at any rate, Mr. Turner promised to carry down the subject to a more recent period, a promise he did not live to fulfil. A second volume has however been prepared and published by Mr. Parker of Oxford.

TURTONA, a genus of Conchiferous Molusca, named by Mr. Hanley after Dr. Turton. There is but one species, T. minutus, which has been separated from the genus Kellia. The shell is oblong, inequilateral, anterior side very short; ligament concealed between the valves; hinge-teeth 2-2. Animal with the mantle open in front; foot large, keeled; siphon, single, slender, elongated, protruded from the long end of the shell. It is found in Great Britain; also in Norway and Greenland. (Forbes and Hanley, British Moluscoa; TUSCANY. The territory of Luca fell to Tuscany in 1847.

TWICKENHAM. [Middlesex.]

TYPTUS FEVER, TYPHOID FEVER. [Physic, Practice of (Blood, Diseases of), S. 2.]

TYTLER, PATRICK FRASER, was born at Edinburgh on the 30th of August, 1791, the fourth son of Alexander Fraser Tytler, Lord Woodhouselee. He was destined to increase the literary reputation of a family in which literary taste and talent seemed hereditary. After having been educated at the High School and the University of Edinburgh, he became a member of the Scottish Faculty of Advocates in 1813, but he soon abandoned practice for authorship. On the peace of 1814 he accompanied Mr. (now Sir Archibald) Alison and the present Lord-Justice Clerk of Scotland on a visit to the Continent. His first literary efforts were a contributor to 'Blackwood's Magazine;' but in 1815 published in Edinburgh an independent work entitled 'Life of James Cluni, commonly called Admirable Crichton.' The work resolved a second edition in 1823, when an 'Appendix of Original Papers' was added to it. In 1823 he published 'The History of Scotland' (from the Life of Sir Thomas Craig of Riccarton; including biographical sketches of the most eminent legal characters from the institution of the Court of Session by James V. till the period of the Union of the Crowns; and this was followed in 1826 by 'Life of John Wylye,' published anonymously. It was about this time that, on the earnest suggestion of Sir Walter Scott, who had at one time thought of undertaking the task himself, he began his great work, 'The History of Scotland.' The first volume was published in 1828, and the work was completed in nine volumes in 1845. It has since been passed through several editions, and is recognised everywhere as the standard History of Scotland—the only work in which Scottish history is treated at full length on the basis of authentic materials, and in a calm and accurate style distinct from a merely popular manner. It commences with the accession of Alexander III. to the Scottish throne in the 13th century, and brings down the narrative to the union of the crowns in 1606. While writing this work, Mr. Tytler resided sometimes in Edinburgh, sometimes in London, collecting materials in both places. During the time that the work was in progress he threw off other smaller historical works, of which the following is a list:—'Lives of Scottish Worthies,' in 2 vols., 1831-32; 'Historical View of the Progress of Discovery on the more Northern Coasts of America,' published in Edinburgh in 1822, and recently re-edited in America; 'Life of Sir Walter Raleigh,' 1833; 'Life of Henry the Eighth,' 1837, and 'England Under the Reign of the Red Monarch,' published by Mary, illustrated in a series of original letters, with historical introductions and notes, 1839. Mr. Tytler also wrote the article 'Scotland' for the seventh edition of the Encyclopaedia Britannica, and the article has since been re-published as a useful abridgment. In recognition of claims so well founded, Sir Robert Peel's government conferred on Mr. Tytler a pension of 2000 a year. In politics he was a Conservative. Though an Episcopalian, he took much interest in the Scottish Presbyterian movement of 1834-43. In private life he was much beloved for his social qualities. Towards the close of his life he suffered much from ill-health, and went abroad for a time. He returned to Edinburgh, and died on the 24th of December 1849. He was twice married, and left two sons and a daughter by his first wife.

UDORA, a genus of Plants belonging to the natural order Hydrocharitaceae. A proable species of this genus has been recently introduced into England, and described by Badingon under the name of Anacharis alnus maritimus. The following is his description in the 'Manual of British Botany':—

It has its leaves 3 in a whorl, oval-oblong, obtuse, serrulate (the male flower is unknown), the female flower with a tube 3 or 4 times longer than the sepals, five greenish-white filaments, sessile, stamens reflexed. The stem is long, branching; whorls of leaves many included. Flowers subtended by a leaf-like bract placed within the whorl of leaves. Flowers very small. The sepals tinged with green and pink externally, incurved, hooded, with a narrow distalmost margin. The petals are flat, diaphanous, recurved, and oblong. Filaments at first curved onwards, their points placed under the hood of the sepals, afterwards erect, linear, blunt, diaphanous; stigmas recurved, linear, or deepily bifid; sepals, petals, and stigmas, of about equal length; the style adnate on three sides to the tube.

This plant was first observed in Great Britain by the late Dr. Johnson of Berwick-upon-Tweed, in the river Whiteadder, in Berwickshire. It was afterwards discovered in a canal near Nottingham, and subsequently in many other places. Although at first not known, yet late inquiries have led to the conclusion that this plant is the Udera Canadensis of American botanists, and that it has been introduced into this country by means of the timber that is brought from the New World. Its power of retaining its vitality adapts it to bear so long a journey without destruction. The peltilliferous plants have alone been seen in Great Britain. Its power however of reproducing itself by buds is so great that it has already become a serious pest in the rivers, canals, lakes, and ponds with which it has been introduced. Anacharis alnus maritimus is one of those plants in which a circulation can be seen, and has afforded some observers the means of more closely watching these vegetable movements than by any other plant that yet has been observed. It has been inferred by Dr. Branson and others, that the movements of the cells-contents of this plant are produced by cilia. Mr. Wenham however regards this movement as originating in the molecular activity of the protoplasmic endoplasm. (Badingon, The Life of Botany, New Water-Weed; Branson and Wenham, On the Sap-Circulation of Anacharis alnus maritimus, in vol. iii. of the Quarterly Journal of Microscopic Science.)

UMPERI. [Arbiration, S. 2.]

UNION. [S. 2.]

UNITED STATES OF NORTH AMERICA, a Republic, formed by the federal union of States and Territories.
It occupies the middle portion of North America; and extends between 32° and 49° N. lat., 67° and 120° W. long.; from the Atlantic Ocean on the east to the Pacific Ocean on the west. It is bounded N. by British America, S.W. by the republic of Mexico, and S. by the Gulf of Mexico. The boundary line between the United States and British America is marked under Usur in States, S. I., the greatest width of the United States from east to west is 990 miles, the greatest length from north to south is 1730 miles. The entire area of the United States has been very differently estimated. As estimated by the United States authorities for the Census office in 1850, it amounted to 3,208,921 square miles. But a more elaborate and careful estimate made by the United States Topographical Bureau, January 1854, reduces the area to 3,935,166 square miles, and if to this be added the additional territory of 27,500 square miles, ceded by Mexico by treaty in July 1854, the total area at the present time will be 3,963,656 square miles. The population in 1850 was 22,191,676, or 7.90 to a square mile: but this does not include the native Indians, who were estimated by the Indian Commissioner in 1853 at 400,704. The following table shows the States and Territories comprised in the Union, with the extent of each, the number and character of its population in 1850, and other particulars.

The areas of several of the States and Territories in this table are given from the new computations made by the United States Topographical Bureau, and recently made public in the 'Statistical View of the United States,' drawn up and printed by order of Congress.

The physical geography of the United States has been given generally under America; and more particularly under the heads of the several States and Territories; of the rivers Columbia, Minnesota, Missouri, Arkansas, and Rocky Mountains, &c.; the lakes Erie, Ontario, &c. The total area of the United States, as already stated according to the revised calculations of Colonel Abert, of the United States Topographical Engineers, is 3,963,656 square miles, which he thus apportions—Area of the Pacific Slope, or of the region watered by rivers falling into the Pacific, 792,702 square miles; the Mississippi Valley, 1,517,593 square miles; and the region whose waters fall into the Atlantic, 932,960 square miles, of which 514,415 square miles belong to the Atlantic slope proper, 112,649 square miles to the Northern Lake region, and 325,333 square miles to the region whose waters fall into the Gulf of Mexico, east and west of the Mississippi. The main shore line of the United States on the Pacific coast amounts to 6291 miles, on the Pacific to 2281 miles, on the Gulf of Mexico to 3467 miles; the island shore on the Atlantic to 6328 miles, on the Pacific to 702 miles, and on the Gulf of Mexico to 2217 miles, giving a main shore line of 12,059 miles, and an island shore line of 9247 miles.

The following table taken, with a few slight changes to render it more readily understood by English readers, from the official 'Compendium to the Census,' will show at a glance the extent of the territorial acquisitions, and the occasions on which they were made:

The commerce of the United States has gone on rapidly extending, until next to that of Great Britain it is the largest in the world. In the year ending June 30, 1866, the total imports of the United States amounted to 314,633,942 dollars; the exports to 326,964,908 dollars; of which 310,868,330 dollars were of domestic produce, and 16,378,678 dollars of foreign produce. Of the foreign trade, consider-
ably more than half is with Great Britain and its dependencies. The total amount of tonnage engaged in the foreign trade was 9,871,062. The total number of American vessels entered from foreign countries in 1856 was 10,507, of foreign vessels, 11,375; the clearances during the same year were, of American vessels 10,592, of foreign vessels 11,186. The registered tonnage of the commercial navy was 2,401,403. The crews of American vessels cleared out numbered 122,971 men and 1070 boys. There were in 1857 of canals 4796 miles; of navigable rivers and navigable miles connected 10,000 miles.

The naval and also the military forces will be found under MILITARY AND NAVAL FORCES, S. 2.

The revenue of the United States for the year ending June 30, 1857, was 3,631,311 dollars, of which 60,975,900 dollars were raised by excise duties, and for the same year was 70,852,724 dollars. Of this 6,943,896 dollars was for interest on and redemption of the public debt, which amounted to 30,958,909 dollars.

The following is a list of the Presidents, continued after those previously given (v. xxvi. p. 12):——

10. John Tyler, 1841 to 1845
11. James Knox Polk, 1845 to 1849
12. Zachary Taylor (died in office), 1849 to 1850
13. Millard Fillmore, 1850 to 1853
14. Franklin Pierce, 1853 to 1857
15. James Buchanan, 1857

From the establishment of their position as an independent republic until the present time, the United States have been chiefly occupied in the development of their vast resources. Much has been done in the year 1866 towards the improvement of navigation, and the advancement of science has been a principal topic of conversation. The discovery of the 'Penny Cyclopaedia,' after explaining generally the processes of observation and reasoning by which the science of physical astronomy has attained its present degree of perfection, gives a series of brief historical notices of the discoverers in astronomical science, and of the most important of the observations and developments which have been brought down to the year 1830. The most important of the instruments by which the processes of astronomical observation are carried on are elaborately described, with the addition of figures accurately drawn, under the heads Celestial ASTRONOMY; EQUATORIAL INSTRUMENT; REPEATING CIRCLE; and Sextant; and also under PENDULUM and TELESCOPE.

The collection of revolving bodies of which the sun is the centre, is described generally under the head SOLAR SYSTEM; and the Newtonian theory of that system is explained under the head GRAVITATION. The sun and each of the large planets are described separately under their respective names, Sun, Mars, Mercury, Venus, &c. The earth and the earth's satellite are described under the heads Earth, Astronomical; EQUATORIAL INSTRUMENT; REPEATING CIRCLE; and Sextant; and also under PENDULUM and TELESCOPE.

So far as to the solar system, the starry heavens have a distinct article Stars, Double Star, Cluster of Stars, Nebulae, and there is also an article on the obscure masses of stars called the Milky Way.

The additions made to astronomical science since the completion of the 'Penny Cyclopaedia' have been as numerous and important, that a detailed account of them would be scarcely possible except in a work wholly devoted to the subject. It may be sufficient here to indicate broadly some of the leading facts which have a general rather than a purely scientific interest, yet which will serve to illustrate the revolution in astronomical science.

First in rank we may place the determination of the motion, or movement of translation, as it has been termed, of the entire solar system in space. The possibility of such a movement was suggested by Bradley in 1748, and this hypothesis was dismissed by subsequent astronomers, but the elder Herschel was the first who sought by actual observation to verify or disprove the notion. His observations, which extended over more than twenty years (1783-1806), led him to conclude that such a movement did really exist; and as our solar system is moving towards the constellation Hercules, it remained, however, long a mere hypothesis. [Solar System, vol. xxii, p. 196.]

The first important step towards its confirmation was made by Argelander, in a paper published in the 'Mémoires' of the Imperial Academy of St. Petersburg for 1837. By comparison of the proper motions of 290 stars given in his own catalogue of 600 stars observed at Abu, with those of Bradley as given in the 'Fundaments of Astronomy,' Argelander verified the fact of the motion, and found the duration of the movement which the system would be expected to be situated in the same constellation as Herschel supposed. Other astronomers pursued the enquiry with great zeal and industry, but the decisive step is ascribed to another Russian astronomer, Mr. Litter, of Petersburg, whose paper (On the MMORPHOGENIC STANCE OF THE PRECISION WITH BEUGER WINDIGEN DER SEHTE) was printed in the St. Petersburg 'Transactions' for 1842, was regarded as having set the question at rest, and was, on account of its importance, awarded the gold medal of the Royal Astronomical Society of London, in 1850. The results of these researches of Argelander and Struve are thus summed up by the elder Struve in his 'Études d'Astronomie Stellaire,' p. 105, [see Grand History of Physical Astronomy, p. 507.]

"The movement of the solar system in space is considered to be a point in the celestial sphere, situated on the right line which joins the two stars of the third magnitude, w and h, in Hercules. The velocity of this motion is such, that the sun, with the whole corps of bodies depending on him, advances annu-
ally in the direction indicated, through a space equal to 1,632 radii of the terrestrial orbit, or 154 millions of miles."

The observations which led to this great discovery were all made on stars of the northern hemisphere. It was most significant that at that time no more than 274 stars were the subject of the researches of Argelander and Struve, and that the motion thus discovered in the great system of the stars would be of the same order as that of the stars of the northern hemisphere. This laborious task was under-taken by Mr. Galloway, Employing the catalogue of 64 stars of Argelander and Struve, the observations were made on 172 stars observed by Mr. Henderson at the Cape of Good Hope, with the older determinations of Bradley and Lacaille, he arrived at almost exactly the same conclusions as Argelander and Otto Struve; the reality of motion being proved, and the point of motion being nearly identical. For this work Mr. Galloway received the gold medal of the Astronomical Society. Finally, to remove all possibility of doubt, if any remained, Mr. Main contributed to the Astronomical Society, in 1853, a catalogue of 765 stars observed at Greenwich, in which the accuracy of the inves-
tigations of Argelander and Struve was fully established.

The fact of this rapid movement of the entire solar system in space is of great importance in practical astronomy; while the study of the question of whether there does or does not exist a general centre of gravity, to which is subjected not only our own solar system, but the whole stellar system, is one of the most important questions of astronomy. The reality of solar system has attempted to arrive at conclusions more or less certainly the subject, but as is well said by Sir John Herschel, noticing some of their theories: 'In the present defective state of our knowledge respecting the proper motion of celestial bodies, and the direction in which it is to be sought, we should regard as to a certain extent premature, though by no means to be discouraged as forrunners of something more decisive.'

A subject which has long been one of primary interest in astronomy, is that of the constitution of the central body of our solar system. The then actual condition of our know-
At its peak, the spots on the sun have been carefully watched by many skilled observers. The observations and investigations of Dr. Bohn, Mr. Dawes, and others, have been particularly valuable. One of the chief points ascertained was that, by Mr. Dawes (in 1859), of the rotation of the sun's spots.

The latest important contribution on this particular subject was that of M. Schwabe of Dussan, which obtained for the sun's rotation at 4.9 degrees per month. It has already been noticed that the Sun is keeping for the period of the astronomer a continuous record of the changeful progress of the spots upon his disc.

We may add, that by the very refined means now in use, photographs and daguerreotypes are now obtained almost exactly parallel to the position of the spots on the sun, but even of Jupiter and his belts, and of numerous astronomical phenomena of a kind which, from their fugitive nature, could only be hitherto described in words or depicted from memory.

With respect to the lunar atmosphere, a negative opinion has likewise been arrived at; though whenever an instrument of increased power, or a stellar phenomenon, appears likely to afford a new or more precise test, it is carefully brought to bear upon the question. Thus a delicate test is the exact observation by a telescope of high magnifying power of the occultation of a planet. If the moon were enveloped in an atmosphere, there would be some change of form or brightness in the planet, owing to atmospheric absorption or reflection of the moon's light upon the immersion, or reappearance of the planet.

None such however has been observed with the powerful instruments which have been employed for the purpose of late years. On the contrary, the intensity of the moon's light, by the most minute difference, does not appear to be diminished in any respect whatever, even with the slightest deflection of the planet's light, and in precise accordance with calculation as to time.

Another question of great interest has also been solved; that of the true heat, or the actual sensible heat, of the light of the moon.

Various experiments had at different times been made with a view to determining whether the lunar rays gave any appreciable warmth, but without success. At length, in 1846, Signor Meissoni, an eminent Italian astronomer, renewed the experiment on the cone of Mount Vesuvius, and succeeded, by means of a large lens of peculiar construction, in obtaining satisfactory indications of elevation of temperature. Some doubt however remained as to the accuracy of the experiment, but it was dissipated by still more distinct evidence of the radiation of heat from the moon being obtained by Professor Piazzi Smyth. To resolve this and some other astronomical, meteorological, and magnetic problems, Mr. Smyth established himself, during the summer of 1866, on the summit of some mountain near Saronde, to which he had ascended, for the purpose of placing his instruments beyond the obstructing influence of the earth's grosser atmosphere. His upper station was 10,700 feet, his lower 8840 feet, above the level of the sea, and at the lower, as well as at the upper station, the warmth of the moon was distinctly felt.

A point of great interest to astronomers—what is known as the long inequality in the moon's epoch—has been satisfactorily elucidated by the labours of Professor Hansen of Gottha and of Mr. Airy, the Astronomer Royal (1846-49); the latter of whom has also discovered and explained a new lunar inequality depending upon the action of the planet Venus.

The statement of the reasons of Messrs. Airy and Hansen was not put out of place in a non-mathematical and non-technical like the present one, but it is not so indicative of the importance of these discoveries, (in the words of Mr. Grant, 'History of Physical Astronomy'), that they "completely account for the errors in the tables which had so long perplexed the astronomers and mathematicians of Europe. The lunar inequalities may therefore be considered as divested of all serious embarrassment."
group, not accidentally, but in the course of a laborious examination of that portion of the heavens, undertaken in the full expectation of finding such a body there. For, on the discovery of the second planet, Olbers conceived and published the idea that these two small planets might be fragments of a large planet which had been broken up by some great catastrophe; and if so, that these, and most likely other fragments, were describing round the sun elliptical orbits, the existences of such moons must fall near the same point. Impressed with this idea, Olbers, after a search prolonged for nearly five years, discovered, as we have said, a fourth planet—a third had been meanwhile discovered accidentally—but the laboratory to no other astronomer was so rewardingly successful, and any systematic search was gradually abandoned. Nearly forty years elapsed before a fifth, Astrea, was added to the group of minor planets. A year and a half later another was discovered; and now, after the lapse of little more than ten years, no less than forty-seven more have been found—in making in all fifty-three, of which forty-nine have been discovered from the 1st of July 1847—and all (at least since the fifth of the series) as the result of a systematic exploration made with telescopes of great power.

Without further reference to the hypothesis of Olbers, that these minor planets are the fragments of a disrupted planet, we may notice the remarkable coincidence or conjunction of their orbit respecting various dates, as quoted by Humboldt in his 'Cosmos,' Sabine's translation, vol. iii., p. 374.) "It appears to testify in favour of a real or inherent connection between all the members of the entire group of the small planets, that, if we figure to ourselves the natural dimensions of their orbits as forming interlacated rings, these rings are all so interlinked, that by taking hold of any one, all the others would be lifted by, or found suspended on it." The whole of these minor planets are what are termed telescopic rings, being invisible to the naked eye. The diameter of the largest is indeed probably less than 600 miles, but it is scarcely necessary to add, that if the whole 63 at present known—and probably more will yet be found—are fragments of one shattered planet, it must have been very large.

The four minor planets which were first discovered are all noticed under Vesta; but we give a full list of them, arranged in the order in which they were discovered, with the names of the discoverers, and the date of their discovery.

51. Calypso Lassell April 4, 1858.

The planet Saturn, from the wonderful appendices connected with it, and the general beauty as well as scientific interest which it presents to the astronomer, has always been an object of careful examination and study; and it might well have been supposed that little additional information was attainable respecting its external characters, did not every increase of telescopic power afford evidence that the field of astronomical discovery is in a measure inexhaustible. The first of the recent discoveries was made in 1848. During the autumn and winter of that year the rings of Saturn disappeared, and astronomers seized the opportunity to observe the planet with unusual care, in order to discover any proof which would seem to lead to a view of ascertaining with greater precision the diameter, if any, of his diameter from a true ellipse. In the course of this examination Mr. Bond, of Cambridge, Massachusetts, U.S.A., succeeded in discovering a very large satellite, probably some 16,000 miles in diameter, and consequently eight satellites of Saturn—but seventh is distance from the planet. This satellite, to which the name of Hyperion has been given, was first seen by Mr. Bond on the 1st of September, 1848, but its true character was not recognized by him till the 19th of that month, when it was discovered by Mr. Lassell on the 18th of September. The sidereal revolution of this satellite round the planet is 24 days, 4 hours, 20 minutes, its mean distance in semi-circle, 3 Saturns = 20:08; the revolutions and mean distances of its other satellites are given under Sat.-lune.

The other discovery—that of an inner dark, dusky, diaphanous ring, lying between the bright ring and the bed of the planet, but unattached to either—was made nearly two years later. On this occasion Mr. Bond was again one of the first discoverers, but several European astronomers detected it very nearly at the same time; and the actual priority of is of the consequence, as it is certain that the inner ring had been observed by Dr. Galilei of Bologna in 1610, and that of this by Encke in the 'Naturwissenschaftliches Archiv,' though somewhat unaccountably it had been suffered to entirely escape notice. But the discovery of this inner ring led to a more searching scrutiny of the other rings, and to the detection by our countryman, Mr. Dawes, and Mr. Heath, of an additional ring in November and December, 1851. Of Otto Struve was again led to the conclusion that the inner edge of the interior bright ring is gradually approaching the body of the planet, while the total breadth of the bright rings is increasing. Mr. Main, however, having seized upon a very large number of measurements of the rings with double-image micrometer, during the years 1856-55, for the purpose of testing Struve's hypothesis, failed to detect any increase of width, and regards Struve as mistaken.

In the article Uranus, that planet was said to have six satellites, but of which only two had been seen, except the discoverer of Uranus, Sir William Herschel. In 1847-48 two, perhaps three, of these satellites were seen, by Otto Struve, and Mr. Lassell; and in October and November, 1852, Mr. Lassell discovered seven satellites of Uranus, both apparently nearer to the planet than the first satellite of Sir William Herschel; the periods of revolution of the new satellites are respectively 4 days and 18 days; while the first of Herschel's is about 6 days. After what has been said, it is scarcely necessary to add that none of the satellites of Uranus can be seen except with first-rate telescopes.

But far more remarkable than either of these discoveries is the discovery of Neptune—as Encke expressed it, in a passage quoted by Humboldt, "the most brilliant of all planetary discoveries, because purely theoretical investigations established the antecedent prediction of the existence and the place of the new and yet unknown planet." In the motion of the planet Uranus, certain irregularities had been seen...
years observed, which could not be explained by the action
of the planets then known to exist. Several astronomers
had directed their attention to this enigma, as Bessel termed
it; but no real advance had been made towards solving the
problem when two young men, Adams and Leverrier, and
Le Verrier of Paris, devoted themselves, unknown to each
other, to the task—one of enormous labor, and requiring
great skill in the higher mathematics—of arriving by calcu-
lation at the source of the perturbation. Each arrived at the
same result in the summer of 1845, namely, that a new
planet outside Uranus, and each succeeded in indicating
nearly the same position as the spot near which it would be
found. The steps in the discovery are so fairly indicated
by Bessel, that we borrow his summary as that of a
conversation with Prof. Challis, in September, 1845:
The question was directed to Dr. Adams, of Harvard College, which he had obtained for the perturbing planet, before Pro-
fessor Challis, in September, 1845, and the same, with some
modifications, in the following month, October 1845, before
the Astronomer Royal,—still without publishing anything.
Some weeks later, and at a period long after the greatest
intention of interfering with some fresh corrections relating to a diminution of the
distance, in the beginning of September 1846. The young
Cambridge geometrian, continues Bessel, "has ex-
pounded a theory of new modesty and simplicity, a
subject of this championship successes of labours, which
were all directed to the same great object:—I mention these earlier dates merely to show that my results
were arrived at independently, and previously to the
publication of M. Le Verrier, and now I am inclined to believe, with his just claims to the honour of the discovery; for
there is no doubt that his researches were first published to
the world, and led to the actual discovery of the planet by
Dr. Galle: so that the facts stated above cannot detract in
the slightest degree from the credit due to M. Le Verrier;"
Le Verrier having communicated to Dr. Galle the results
at which he had arrived, and begged him to seek for the
predicted planet, Galle at once directed the great telescope
of the Berlin Observatory to the spot indicated, and, on the
23rd of September 1846, had the exquisite delight—the
greatest pleasant which an astronomer could experience—of
discovering there the new planet for which he was looking.
The name of Neptune has been given to the planet with the
full consent of all its discoverers, and was, I believe, first
thought they could perceive the new planet to be surrounded
by a ring, but there is little doubt that this was a mistake.
On the 10th of October 1846, however, Mr. Lassell per-
ceived what he believed to be a satellite of Neptune, but
the planet was then rapidly approaching the end of its vis-
ibility for the season, and he was unable to determine the
point. On the reappearance of the planet, he again directed
it to its great 20-foot reflector, and on July 6-8, 1847, he
reconciled with certainty, the first of Neptune's satellites.
In August 1850, Mr. Lassell believed that he saw a second
satellite of Neptune, but the discovery has not been con-
firmed.
Neptune is the most distant planet at which the existence
is known. It is 3,040 million miles from the sun in 2,068
million miles, or above thirty times the mean distance of the
earth; and more than 1,000 millions of miles farther off than
Uranus the next most distant planet (or, the mean distance
of the earth being taken as 1), that of Uranus is 19. Astronomers at the Paris Observatory, after his final res
of a sidereal revolution is 60,126 days 17 hours five minutes, or
164 years and 226 days. Its diameter is 36,000 miles, yet
so great is its distance, that it can only be discovered with
a very powerful telescope. The mass of Neptune is about
21 hours 4 minutes, at a mean distance from Neptune of
236,000 miles—or about 2000 miles less than the mean
distance of the moon from the earth.
Comets have during the last few years engaged no small
time of attention. Of which, if it can be said that a comet, whose return was predicted, appeared at the antici-
pated periods, but every year some new comets mostly
telescopic—have become visible. But the most astonishing
cometary phenomenon, and one wholly unanticipated — of
which the possibility even had never suggested itself to
any one—was the separation into two parts of Biela's comet.
This comet, which has a period of revolution of 66 years,
became visible in November, 1846, and remained visible for
several months. In April, 1847, Mr. Hind noticed a kind of protuberance in the comet; on the 26th, it
was seen by astronomers in North America to have separated into two, each being in fact a distinct comet, with its
own motion and light. The protuberance was not ob-
served in Europe till January, 1847. The two parts
which were unequal in size but similar in form, moved in the same
direction, with an interval between them of empty space, at
first equal to about 3, but which afterwards increased to
about 5000 miles. Each continued as long as they were visible, sometimes one, and sometimes the other being
the brighter. The smaller comet disappeared towards the
end of March, the larger one continued visible till the 20th
of April. The phenomenon, of course, excited great interest,
and the next periodical appearance of the comet was anxiously
expected by observers, all being desirous to know whether
it would re-appear as a single or a twin comet. It re-appeared
at the calculated period, and as a twin comet. On the 22nd
of May, the right hand portion was seen by Signor Secchi;
the other portion was first seen on the 15th of the
following September. Since they were last seen, in the early
part of 1846, the distance between the nuclei had much
increased, while the same alternations of brilliancy occurred.
The two comets were last visible in August 1850; since
then, the two parts have not been observed together; and
indeed, the severance of the two portions appears, from
a comparison of the various observations, to be complete
and permanent. The next appearance of the comet, which
will be in April, 1869, will probably go far to settle the
question.

The number of comets recorded as having been seen at
various times and in different countries amounts, according
to the reckoning of Mr. Hind, to 607. Dr. Michelson, in
his Astronomical Catalogue, 1847, at a meeting of the
Astronomers at the Royal Observatory, stated that
there are 3 comets whose return is certain (Halley's,
Encke's, and Biela's comets), 5 probably periodical, and 19
for which elliptical orbits have been calculated with some
degree of probability, making the total number of periodical
comets 27. The number of comets whose orbits have been
calculated down to December 31, 1853, amounted to 4
periodic comets, and 97 comets the returns of which to the
perihelion had not been established with absolute certainty,
making altogether 201.

One of the grandest comets mentioned in history is that
which made its appearance in the middle of the year 1284.
A very brilliant comet which appeared in 1566 is suppos-
ed by Mr. Hind to be identical with the former. This comet
was discovered in November, 1565, and was last seen in
August, 1568, and August, 1650, there being an uncertainty
of two years in the items on which the return of the
comet is calculated.

In the division of stellar systems, beyond the region
of the solar system, great activity has been displayed by astron-
omers. Zones of stars, down to those of the ninth magni-
tude, double, and multiple, and variable stars, have been
with minuting labour and perseverance observed and catalogued
by Laland and Lacaille (whose catalogue, and another of
great value, have been published by the British Association), Bessel,
Argelander, Airy, Lament, F. G. W. Struve, Chacornac,
Rümker, Cooper, and many more men of profound attain-
ments and indefatigable zeal. The value of star-catalogues
for the future is hardly beyond all question. Of the curiosity
preparation brings to light, it may be sufficient to mention as
an illustration, that the great catalogue of Mr. Cooper, made
at his observatory, Markree, Ireland, and published by the
aid of the parliamentary grant to the Royal Society, shows
that "no few of the stars previously catalogued are now
missing." On the other hand new stars have suddenly ap-
peared, and whilst Sir John Herschel was at the Cape of
Good Hope, he saw the star a Argus increase from the
20th magnitude to the 8th. In the appearance of new and the disappearance of old stars, the
mentioned the hypothesis of F. G. W. Struve, that light in
its passage through the boundless regions of space becomes
successively weakened and eventually extinguished—a theory
which, if it could be proved, would open a wide field for
reflection and investigation.

One of the most important recent additions to stellar astron-
omy is Sir John Herschel's "Results of Astronomical
Observations made during 1834-36, at the Cape of Good Hope; being the completion of a Telescopic Survey of the Whole Surface of the Visible Heavens, commenced in 1825, which was published in 1847. The first part of this survey was made in the northern hemisphere, as the continuance of his father's 'Survey of the Heavens,' which occupied most of his famous catalogue. Sir John Herschel's four years' residence at the Cape of Good Hope, in the words of Humboldt ('Cosmos,' iii. 200), 'constitutes an epoch in respect to the more exact topographical knowledge of the southern heavens; his telescope and the observatory which resulted from it for double stars, which, with a few exceptions, had never been observed before.' But double stars formed only one of several departments of astronomy which Sir John enriched by his observations and investigations. So vast, indeed, was the field opened up by his researches, that it took the author nearly nine years to digest them and prepare the results for publication in a regular form.

Passing to the nebula, we find the greatest advances due to the construction of the magnetised telescope which Lord Rosse set up on the lawn in front of his residence, Birr Castle, near Parsonstown, in King's County, Ireland. The lenses of this enormous instrument—which has 6 feet aperture and 64 feet focal length, and is by far the largest telescope ever formed—was instrument constructed, under his lordship's personal superintendence. As was expected, it was found to possess a far greater amount of space-penetrating power than any previous telescope. By means of it Lord Rosse has succeeded in resolving the nebulae which had remained hitherto resolvable only by the naked eye. Besides showing that these hitherto unresolved nebulae were wholly composed of stars, Lord Rosse's telescope disclosed many unexpected peculiarities of structure—as, for example, a very remarkable but well defined spiral arrangement—in several nebulae; a new family of nebulae, &c. as a result of these investigations. The device was, indeed, that it took the author nearly nine years to digest them and prepare the results for publication in a regular form.

The researches of the celebrated Sir John Herschel on the teaching of language, and the results for publication in a regular form.

We may perhaps not unaptly conclude this sketch by a brief allusion to a few of the labours of Mr. Airy at the Royal Observatory. We have already dwelt at some length on the great improvements that have been made in the science of the heavens and in new instruments of greatly increased power, and of the most refined character, have been introduced. The yearly observations are published in a form and with a regularity never before attempted. He has also procured the reduction under his own superintendence of the Greenwich Lunar Observations from 1760 to 1830, and the uniform reduction of all the Observations of the Planets made at Greenwich during the same period—works of enormous labour, but of inestimable importance—the former of which was published in two large quarto volumes in 1846, the latter in a very thin one in 1846.

Telescope. He also introduced and perfected, in a series of elaborate experiments, the method, first practised in America, of determining the longitudes of distant places by direction and time of transit; the ephemeris. By these means he successfully determined the longitudes of the principal observatories in the British Islands and on the Continent; and he in like manner connected the observatory with Deal, and with many other maritime and inland stations, so as to make the whole system one continuous one. And, in the last volume of the Greenwich Nautical Almanac, the true Greenwich mean-time for maritime and other purposes.

We ought also perhaps to notice that, among other works of M. Le Verrier, which he published under the direction of M. Dumas, and which was reprinted in the latter in a very thin one in 1846, the latter in a very thin one in 1846. He also introduced and perfected, in a series of elaborate experiments, the method, first practised in America, of determining the longitudes of distant places by direction and time of transit; the ephemeris. By these means he successfully determined the longitudes of the principal observatories in the British Islands and on the Continent; and he in like manner connected the observatory with Deal, and with many other maritime and inland stations, so as to make the whole system one continuous one. And, in the last volume of the Greenwich Nautical Almanac, the true Greenwich mean-time for maritime and other purposes.

We ought also perhaps to notice that, among other works of M. Le Verrier, which he published under the direction of M. Dumas, and which was reprinted in the latter in a very thin one in 1846. He also introduced and perfected, in a series of elaborate experiments, the method, first practised in America, of determining the longitudes of distant places by direction and time of transit; the ephemeris. USES, CHARITABLE AND SUPERSTITIOUS.

[Thurso.]

USURY. Although the legitimacy of interest upon moderate and conscienfious terms has long been recognised amongst us, it has, until quite recently, been believed desirable to regulate by law the rate at which it should be taken, and the amount of it that could be allowed. It has now been stigmatised with the odious appellation of usury. [In-

terest, vol. ii. p. 506.] It has been reserved for our own time to carry out a principle which political economists have preached for a century, that of permitting the rate of interest to regulate itself in accordance with the exigencies of the time and the nature of things. The first statute by which some relaxation of the usury laws was made in favof trade, was the 3 & 4 William iv. c. 98, which enacted, that no person taking more than the rate of legal interest for the loan of money on any bill or note not having more than three months to run, should be subject to any penalty or forfeiture. Shortly afterwards the statutes 6 & 7 William iv. c. 41, enacted that bills or other securities should not be void as a higher rate of interest than was allowed by the statute of 12 Anne had been received thereon. The statute 1 Vict. c. 90, next enacted, that bills payable within 12 months, should not for a limited time be liable to the usury laws, and this statute was followed by six others, of which the last (of 9 & 10 Vict. c. 24) preserved the principle of the act. The statutes 2 & 3 Vict. c. 37, enacted that no bill or note, payable within twelve months after date, or not bearing more than twelve months to run, nor any contract the loan of money at a rate of interest higher than that customarily taken thereon or secured thereby, or any agreement to buy or receive or allow interest in discounting, negotiating, or transferring any such bill or note, be void, nor any person so lending be liable to the penalties of the usury laws; but it ordered, that in all cases of usury, the money, or such part thereof as should bear interest at a rate higher than the rate of legal interest, should be recoverable as a penalty for the breach of the contract. The natural laws which regulate the terms on which money can be borrowed are therefore now left to operate freely, and borrowers and lenders are amenable to no other rules than those which govern contracts in general.

UTAH, a Territory of the United States of North America, lying between the 47th and 42nd N. lat., and 109th and 110th W. Long. It is bounded S. and E. by the Territory of New Mexico; N. by the Territories of Kansas and Nebraska; N. by that of Oregon; and W. and S.W. by the State of California. The area of Utah is estimated by the 'Topographical Bureau of the United States,' at 269,710 square miles. The population in 1850 was 11,380 (of whom 24 were free coloured persons, and 26 slaves on route to California), or 0.04 to the square mile: but this does not include the native Indian population, who were estimated by the Commissioner of Indian Affairs in 1853 at 11,500.

Surface, Hydrography, &c.—The Territory of Utah occupies for the most part a vast broken depression, known as the Great Basin, which lies between the Rocky Mountains in the north and east, and the Cordilleran range in the west; these lofty mountains rising in parts above the line of perpetual snow, while across them are only a few difficult passes. On the north of the Great Basin there is no continuous mountain chain, the watershed being formed by an elevated tract of them, known as the Uinta range, which slopes from the west to the east the rocky barrier is broken through by the head streams of the Colorado, the only river which finds its way out of the Great Basin; all the others which flow into the basin from the north and southeast being lost in the plains or in the lakes which occupy the bottom of the basins. The Great Basin is about 500 miles long, from east to west, and little less wide, and some 4000 feet above the level of the sea. Parallel to the main range of the Sierra Nevada and the Rocky Mountains are several inferior ranges, of which the Washbunt Mountains on the east are the most important.

URUGUAY

useful class, and with the facilities for internal communication afforded by the Uruguay, it is the natural entrepôt of the commerce of a vast region of the interior; while its own fertile soil and healthy climate would alone render it, in the hands of a peaceful and industrious people, a great exporting country. At present the trade is chiefly centred in Montevideo. The exports consist almost wholly of the produce of the hedges, as hides, horns, hair, jerked and salted beef, tallow, &c., and do not now probably exceed 1,000,000,000 sterling annually. The imports are chiefly of articles of British and colonial manufactures, &c., and of North America and the East Indies, of considerable but fluctuating trade between Uruguay and Brazil, the Argentine Provinces, &c. The exports of British goods in 1853 amounted to 529,858l. The exports to the United States in 1853 amounted to 308,280 dollars; the imports to 308,446 dollars.

Uruguay is a republic with an elective president, a senate, and a house of representatives; but the actual power is generally centred in the president, who is usually some successful general. The country is divided into nine departements—Montevideo, Maldonado, Canelones, San José, Soriano, Paysandú, Durango, and Cerro Largo.

Montevideo is the political capital, the commercial metropolis, and the largest and most populous city of the republic, and is situated on the eastern side of the river, opposite the town of Maldonado, with a fine barbour, good fortifications, and about 3000 inhabitants: it exports hides and copper. Colonia del Sacramento is a small town, with a harbour, opposite Buenos Ayres. None of the other towns are of any importance.

The Banda Oriental was, during the Spanish supremacy, the name of that portion of the vice-royalty of Buenos Ayres which was situated to the east of the river Uruguay, and was occupied by the Portuguese, and the country called the Seven Missions. The continual civil wars by which the declaration of independence was followed in Buenos Ayres, induced the government of Brazil to take possession of the Banda Oriental in 1815. The republic of Uruguay was formed, and a settlement could be made, a war ensued between the two countries in 1825. Through the intervention of the English government a treaty of peace was concluded in 1826, by which the northern district known as the Seven Missions was ceded to Brazil, and the more exclusive southern district was declared an independent republic under the title of Republica del Uruguay Oriental. But instead of securing peace to the country its independence appears hitherto to have only served to diminish its prosperity; hostilities have been almost of every year period, and this was soon followed by the incursion of troops from Buenos Ayres; the assistance of Rosas, the president of Buenos Ayres, having been invoked by Arieu, one of the unsuccessful aspirants to the rulership of Uruguay. Without the help of the latter party securing a manifest superiority, Brazil was induced by the appeals of Paraguay and other neighboring powers to interfere. In order to show her good faith, Brazil sent ministers to the courts of England and France, with a view to obtain their assistance either as umpires or active agents in compelling the respective parties to come to terms. Those powers accordingly sent some ships of war to the Rio de la Plata in 1845. The English ships blockaded Montevideo till 1846 and the French till 1846, when both England and France receded, and Rosas was soon after deposed in Buenos Ayres. Treaties between the several parties gave peace to Uruguay as far as regarded hostilities with foreign powers, and secured the recognition of the republic by the neighbouring states. But internal discord in the Java party, and the more restless manners of Jacobean Pedro, who for some time resided at Asuncion, led to the loss of the capital, and consequently the fall of the government. On the accession of the new party, Juan Manuel Rosas, the Paraguay was retained and it proceeded to treat with the Paraguay an act of dimensions of Canelones, &c.

URUY. [Chemistry, s. d.]
of the several secondary chains attains an elevation of from 2000 to 3000 feet; and from these diverge cross ridges, which form the main range of the Great Basin. A large section of the basin consists of arid plains, on which artemisias and salicarias are almost the only plants, but in many parts these plains are so impregnated with salt as to be unfit to sustain vegetable life. The most remarkable features of this singular region are the great valleys which are formed in the narrow portions of the range between the mountains of the high country and the bordering mountain range. The valleys of the Wasatch Range are generally confined to a coarse granular sandstone. In some localities the sandstones are overlaid with a coarse conglomerate, which is sometimes partly altered so as to assume the character of a grit or rock. Cretaceous strata of the Lower and Middle Cretaceous are overlaid with clay or marl. Good building-stones are quarried in the vicinity of Salt Lake City. Of the mineral wealth of Utah little is really known. The most important is that of coal and bituminous iron. But the most remarkable is the Great Salt Lake, which is situated in the lowland between the ranges of mountains, and is generally covered with saline water. It is the largest salt lake in the world, and is the continuous source of the Mississippi River. It is a huge lake, with an area of about 2,500 square miles, and a maximum depth of about 20 feet. The lake is fed by several rivers, the principal of which is the Snake River, which flows through the state of Idaho and empties into the lake from the west. The lake is saline, with a salinity of about 25 parts per thousand. The lake is surrounded by a wide belt of salt flats, which extend for several miles inland. The lake is the headquarters of many migratory birds, and is an important wintering ground for many species. The lake is also a source of salt, which is mined on the shores of the lake. The lake is also a source of potash, which is used in the manufacture of glass and other products.
Utah

Utah from its insolated situation must be to a great extent brown upon its own resources, if the peculiarities of its population did not cherish by every means their separate self-dependent condition. Cut off by lofty and difficult mountains from all commerce with agricultural resources little more than sufficient for the supply of its own increasing requirements, and without any staple product or material required by the arts or luxuries of civilized life, it is most likely to have any considerable amount of external trade or commerce; while there will probably be a sufficient stimulus to the growth of such manufactures as are required for ordinary domestic purposes.

With California regular communication is maintained, but only by the most organized and elaborate system of trade, and the produce of Utah. On the other hand, from Salt Lake City to St. Louis, the nearest considerable market, is upwards of 1600 miles. Some modification would undoubtedly be required in order to meet the requirements of those who are not in the habit of traveling. It was not till July of the following year that the first section of the pioneers reached the promised land. The remainder were soon to follow; for although the authorities had engaged to stay in Nauvoo till apprised of the safe arrival of the first missionaries, their old opponents came down, and drove them all out of the city in September 1846.

On taking possession of the site of their new city by the Great Salt Lake, the elders at once set about raising regular government, at the head of which they placed their prophet Brigham Young; and as soon as what they deemed a sufficient number of their followers had arrived, and their territory had become by cession from Mexico a part of the United States, they elected the usual state-officers, and to the federal government to be admitted into the Union as a sovereign state under the name of the State of Deseret. But Congress refused their application, and remanded the state back to a territorial condition, naming it Utah. Brigham Young was however appointed or continued as governor; and the community, though nominally under the laws of the Union, remained virtually independent, and governed by the maxims of the Mormon leaders. In 1856, however, Young, who had appointed a 'Gentile' governor, and the federal government assumed a more direct control. This led to disputes, and at length the federal judges were expelled, and the governor was forced to resign, and the two governments were content to be separate, each so living under a patriarchal dispensation, with prophets, elders, and apostles, who have the rule in temporal as well as religious matters; their doctrines being embodied in the 'Book of Mormon' and the 'Book of Doctrine and Covenants,' revealed to their first prophet, Joseph Smith; that they look for a literal gathering of Israel in this western land; and that here Christ will reign personally for a millennium, when the earth will be restored to its para-}

established in Nauvoo by some opponents of the sect, having published certain scandalous statements respecting him, the town council directed its publication to be stopped and the office to be rased. The editors appealed to the mayor of the city for a warrant against John Smith and his brother. Smith at first refused to obey, and placed the city in a state of defence; but he was induced to surrender in order to prevent a collision between his followers and the community, and to make a pledge of protection from the populace. A mob was however permitted to break into the state jail and murder both Smith and his brother. The Mormons elected a new prophet, Brigham Young, as the successor of Smith, and affairs again became prosperous. Several times the federal government tried to length regularly invested it; and the leaders were forced to undertake that the whole body should entirely quit the state. The prophet and elders now formed the bold resolution to follow their leaders across the vast western wilderness, to the far distant and nearly unknown country lying beyond the Rocky Mountains—there to seek some secluded retreat beyond the reach of their persecutors. They had been promised to be allowed till the spring to make their preparations for the departure of the first or pioneer party; but their enemies became clamorous, and they were obliged to set out in February 1846, while it was yet winter. The sufferings of this pioneer party were of the most terrible and trying kind; but they struggled on resolutely, planting crops, and other things as far as their resources would allow. It was not till July of the following year that the first section of the pioneers reached the promised land. The remainder were soon to follow; for although the authorities had engaged to stay in Nauvoo till apprised of the safe arrival of the first missionaries, their old opponents came down, and drove them all out of the city in September 1846.

On taking possession of the site of their new city by the Great Salt Lake, the elders at once set about raising regular government, at the head of which they placed their prophet Brigham Young; and as soon as what they deemed a sufficient number of their followers had arrived, and their territory had become by cession from Mexico a part of the United States, they elected the usual state-officers, and to the federal government to be admitted into the Union as a sovereign state under the name of the State of Deseret. 4 Y

As we did not notice Nauvoo under Illinois, we may add
to what we have said of it above, that it stands on the Mississippi, 125 miles N.N.W. from Springfield; and that after the departure of the Mormons, Nauvoo became the seat of a colony of French communists, or Icarians, under the direction of M. Cabot, who were however far from successful. Of this there is no trace now. The population has dwindled down to a very insignificant number. The great Mormon temple of Nauvoo was, in October 1846, set on fire by an incendiary and destroyed.

(Captain Howard Stansbury, Topographical Engineers, U.S. Army, to the Far West Great Sioux Expedition, of Utah; Fremont, Report of Expedition to the Rocky Mountains; Lient. J. W. Gunnison, The Mormons, &c.; Statistical View of the United States; Seventh Census of the United States, &c.)

UVAROV, SERGY S EMENOVICH, or OUVAROFF, as the name is written in French, an eminent Russian statesman and author, was born about 1783 of a noble family, and received his Christian name from the Empress Catharine, to whom his father was aide-de-camp. He studied at Göttingen, and in the year 1810 made his first appearance as an author in a Project for an Asiatic Academy, written in French and addressed to the Emperor Alexander, in which he proposed the foundation of a great institution for the study of the languages and literature of Asia. In the course of the year 1813, he was appointed, young as he was, to the curatorship of the university and educational establishments of the district of St. Petersburg, an important office which he discharged with great liberality of action. The Emperor, it is said, remarked in a Russian pamphlet, published at the conclusion of the great struggle in 1814, "is now preparing to emerge from chaos and to consolidate its foundations. A stupid tyranny will no longer oppose itself to the efforts of reason, and on the whole surface of the globe it will be permitted to think." When the Emperor Alexander's views became of a more retrograde character than they had been, Uvarov, after vain offering the introduction of some new regulations relating to education, retired, in 1821, from his curatorship but still retained the post of president of the Academy of Sciences which had been conferred on him in 1816. In the following year he became director of the department of manufactures and internal commerce, and he was subsequently for some years minister of finances. That his influence was not extinct was proved by his being able to establish in 1823 an institution for the instruction of young diplomats in the Oriental languages, carrying out in some degree his early project. After the accession of the Emperor Nicholas he was in 1825 made inspector of Public Instruction, a step which excited some surprise, as the tendencies of the new government were certainly not in favour of permitting the liberty to think. From that time till 1846 Uvarov occupied himself actively in founding museums, botanical gardens, observatories, and educational institutions; and in providing for the better endowment of such establishments, and any deficiency in liberality in their management was attributed rather to the emperor than the minister. In 1846 he again retired from office on occasion of some restraints on education being imposed, of which he did not approve.

The principal writings of Uvarov are rather elegant than profound; they are collected in two volumes, one bearing the title of 'Studies of Philosophy and Criticism,' and the other 'Political and Literary Sketches' ('Études de Philologie et de Critique,' St. Petersburg, 1843, 2nd edition, Paris, 1845; 'Essais politiques et litteraires,' Paris, 1846). All of these essays are in French, except two on philological subjects, one on the poet Nunnus of Panopolis, and the other 'On the Ante-Homeric Age,' which are in German. In the preface to the essay on Nunnus, addressed to Göthe, the author expresses an opinion that it is now time for every author to choose for his instrument the language which is best suited to the circle of ideas he intends to treat." He seems however, in spite of the confidence of his tone, to have been for some time in doubt as to venturing to print in German and before publishing his essay for this last purpose he asks for advice. The tone replied "Never confide to any German the grammatical revision of your manuscripts. Do not forfeit the immense advantage you enjoy in not knowing German grammar; I have been trying to forget it these thirty years." Among the few foreigners who have written in that language, Uvarov is admitted to have been one of the most successful. In French, which was in the time of his youth more familiar to him, he composed the 'Letters to the French,' to be perfectly idiomatic by his French editor M. Léonard Leduc, who in his amusing preface declares with apparent confidence in his own correctness that "everywhere our novels, our plays, our books, whether serious or frivolous, are composed in French." Some of his other essays 'Stein and Pozzo di Borgo,' 'The Prince de Ligne,' 'Venice,' 'rome,' &c., are in themselves of interest and are treated in a light and graceful style which never fatigues the reader. Uvarov is reported to have written memoirs on his own time, which may probably form the best portion of his writings in the eyes of posterity.

UWINS, THOMAS, R.A., was born in Pentonville, London, in 1753. Apprenticed to Smith, an engraver of some repute in his day, he acquired, whilst learning the use of the burin, a certain familiarity with the general principles of design. But having fixed his heart on becoming a painter, he, on quitting Smith, entered as a student at the Royal Academy, at the same time availing himself of the lectures of Sir Joshua Reynolds, in which he was much interested. For some years he was principally occupied in making designs for book engravings, in which he seems to have taken Stothard as his model, though maintaining considerable originality; and in the course of his career he very decidedly power as well as grace. He also made some numerous copies of paintings for the use of engravers. At this time he practised almost exclusively in water-colours, and in 1811 he was elected a member (and subsequently secretary) of the Society of Painters in Water-Colours. Failure of health having led to a temporary abandonment of his profession, he after a short interval commenced practice in Edinburgh as a portrait painter, having prepared himself by making a series of portraits for book illustrations. In 1813 he visited Italy, and the studies he made during his stay led him to commence painting pictures illustrative of the cheerful outdoor life of the Italian and especially of the Neapolitan peasantry. These works painted with a light bright pencil, picturesque in costume, gay in colour, and cheerful in spirit, became at once popular, and their popularity remained undiminished as long as he continued to produce them. As samples of these sunny Italian pictures may be mentioned, "The Mandolins; Dressing for the Festa; Neapolitan Peasants" from his diploma for the Academy of St. Luke at Naples; "Interior of a Saint Maunufact at Naples;" "Festa della Madonna del Arco;" "Loggia of a Vine-dressers cottage in the afternoon of a Saint-day;" "Mountaineers at the Festa of June;" "Teaching a Child the Tarantella;" "Children asleep in a Vineyard;" "Making a Nun." He also painted some English pleasant pieces, as "The Top of the Stule," "The Pet of the Village," &c., but with less success. Later he painted illustrations from popular authors, such as "Don Quixote," "Dorothes;" &c., and still later he essayed a lighter class of subjects, as "Lear and Cordelia in Prison;" "Cupid and Psyche" (painted for Prince Albert); Psyche rescued from the infernal Regions with the Casket of Beauty; 'The Reproof;' "John the Baptist receiving the Messiah as a Child on the Morning after the Baptism;" "Judas;" &c., but these were scarcely adapted to his pencil. Mr. Uwins was elected a Royal Academician in 1836; and from 1844 to 1855 he held the office of librarian to the Royal Academy. He was the appointed keeper of her Majesty's pictures in 1849, and keeper of the National Gallery in 1847, but he resigned the latter situation after two or three years. He died Aug. 25, 1857, at Staines, in Middlesex. In the Vernon collection are two etchings by Mr. Uwins, "The Vineyard in the Claret Vineyards, South of France," and 'Le Chapeau de Brigard;' in the Shepshanks' collection are four more characteristic examples of his pencil—"Italian Mother teaching her Child to Swim;" "A Half Noon Scene at sea;" "Among the Icarians;" The tavoletto Shepherd; &c., and 'Suspicion.'
VALENTIA, HARBOUR OF. [Keray.]

VALERY. [Chemistry, 3. 2.]

VALLEJO. [California, 9. 2.]

VALEYS, LILY. [This, a common name for the Cowslip, sec. 11.]

This plant is too well known to need description. The genus _Convolvulus_, a bell-shaped 6-petalled deciduous perennial; a 3-celled 2-ovuled ovary; a bunt trigonous stigmas; berry with 1-seeded cells; flowers joyous to see. -_C. majalis_, the Lily of the Valley, is a foot high, with two ovate-lanceolate radical leaves. The flowers are racemose, nodding, pure white, globose, bell-shaped, and fragrant.

VAN DIEMEN'S LAND. [Tasmania, 9. 2.]

VANCOUVER ISLAND (or the Victoria Archipelago) lies off the western coast of North America in the North Pacific. It is long and narrow, extending in a direction from south-east 48° 34' to north-west 50° 3' N. lat., and between 122° and 129° W. long., the length being about 2,600 miles, the average width 60 miles. It is overlapped at its southern end by the continental cape of Prince Alexander. Between it and the Strait of Juan de Fuca, five leagues wide, is an entrance running in a east-south-east direction for about 100 miles, widening in several places, containing several bays and sounds, and forming several arms on the continental shore; these, suddenly narrowing, turning northward through an archipelago of small islands, called the Arro Archipelago, thence widening into the Gulf of Georgia, which is the channel through Johnstone's Strait into Queen Charlotte's Sound. Vancouver first discovered this passage in 1792. There are many bays and harbours all round the island. Three islands of the Arro group are separated from the coast of Vancouver Island by sounds supplied with water. The island is sparsely inhabited, and consists of two-thirds of Vancouver Island. At the southern end the settlement of Victoria has been formed, on a harbour termed Camosack, safe and easily accessible for vessels, but having the drawback of being rocky. Vancouver Island contains valuable coal deposits, and several good harbours of considerable depth; but the whole does not extend more than 200 miles.

Nootka Sound, Clayquot, Nininat, all on the western coast. The shores of the island present an alternation of rocky cliffs and sandy beaches. At no great distance from the sea is a compact mass of rugged mountains, whose summits are misted with water clouds. The island is not a considerable quantity of fertile land, covered with good natural grass. There are numerous small tribes of Indians on the island, of whom some have been found of a friendly disposition. The possession of Nootka Sound had nearly given rise to a war with Spain, who claimed it, and had expelled some English settlers from Nootka, but it was at length resigned to England, and has since continued in their hands. Vancouver Island was made over in 1846 to the Hudson's Bay Company by a charter, on condition that they should colonize it; the government reserving the right to reclaim possession of the island for Great Britain within a specified time.

North of Queen Charlotte's Sound lies Queen Charlotte's Islands, between 58° and 54° N. lat. The group consists of three islands extending about 150 miles in length, by about 90 miles in breadth. In these islands are several excellent harbours. At Mitchell Harbour, on the middle island, and at other spots, gold has been found, embedded in quartz sand. The island is supplied with water by several excellent springs. The interior of the islands is hilly and well wooded, the climate is healthy, and the soil remarkably fertile. The islands contain several beds of coal, and several fine specimens of lead and copper have been obtained. At Nimpkish, on the north coast of the same island, there are extensive ranges of white and black coal, and coal has been obtained as far north as the 58th parallel. The entrance of the bay is formed by two steep rocky capes (Galata and Hodrova, or Suganlik), 84 miles sandery. The shores sink gradually to the head of the bay, where in the neighbourhood of the city they are level. The Paravati River (the ancient _Lupara_), which rises in the Salish near Shumla, after traversing the two lakes of Devne, discharges itself by a broad stream into the Black Sea, along the foot of the southern walls of Varna. The distance between the eastern shore of the lake of Devne and the Black Sea is little more than half a mile. It has been in communication with the Black Sea by a narrow river, which supplied the city with fresh water. The two lakes of Devne, between the Black Sea and the eastern shore of the lake, are little more than half a mile.

Varna is a wretchedly built town, surrounded by old stone walls and a dry ditch. It is a place of considerable trade, the exports of corn, barley, tallow, eggs, and other Bulgarian produce, amount in value to about 600,000. Austrian steamers between Constantinople and Galata put in at Varna. Under the walls of Varna the Sultan Murad II. in 1444 defeated the Hungarians under King Ladislas (nearly 80,000 men) and John Huniades. The Hungarians took Varna in 1826. The Anglo-French army encamped in Varna and its environs in the summer of 1854, previous to its embarkation for the Crimea.

VARNA. [Tanaceto.]

VENCE. FACIUS. This writ, and also the other writs referred to under this head (vol. xxvi., p. 214), the _disgraces_ and _habeas corpora juratorum_, have been in effect abolished by the Common Law Procedure Act, 1853; which also enacts that the order of procedure and the punishment of contempt shall be by an order of court, and not by the ordinary procedure of the Court of Arches. The _Commentaries_, Mr. Kerr's ed., vol. iii., p. 380.]

VENUS FLY-TRAP. [Dionaea.]

VERNAL GRASS, SWEET. [Anthozoanthum.]

VERNON, ROBERT. Though possessing technically no title to an entry being named in the Register of the National Gallery of British Art, Mr. Vernon claims an honourable place in this work. The so-called 'National Gallery' of paintings was founded in 1834 by the purchase by Lord Liverpool's government of the collection formed by Mr. Angerstein. This collection included nine pictures by British painters—the 'Marriage à-la-Mode' of Hogarth; that painter's portrait; Lord Heathfield by Sir Joshua Reynolds; and Wilkie's 'Village Festival.' In the course of the next twenty-three years there were occasional bequests or presentations of English pictures, but not a single English picture was added to the national collection by purchase: the entire number of British pictures in the National Gallery in 1847 was only forty-one, and several of these were portraits of unknown or insignificant persons by second-rate artists, or works of little artistic excellence or general interest. In every other country the possession of worthy specimens of the pens of the chief painters of that country had been deemed the essential feature of a national collection; here the National Gallery, according to the official estimate, was to be a gallery of the works of the 'Old Masters' of Italy and Holland.

It is to Mr. Vernon that the country is primarily indebted for what has been done towards placing matters on a more rational and satisfactory footing. Born in 1774, he by diligence, perseverance, and skill, during a long commercial career, raised himself from very humble to very affluence circumstances; earning at the same time a high character for honesty, zeal, and humanity in his intercourse with the public. Having a great fondness for pictures, he began, as soon as his means permitted, to indulge his inclination by purchasing some; and following his own taste he selected the works of English artists. In the course of time he was enabled to buy till every room in his house was filled. He now conceived the design of presenting his pictures to the nation, in the hope that if kept together they might serve as the nucleus of a gallery of British art. With this view he sold such of his pictures as he deemed undeserving of such a destiny, and purchased or commissioned (in nearly every instance direct from the painter) fresh examples of the masters he most
admirer, then—not waiting to make it a posthumous gift—he offered his collection to the government, requesting that all those pictures might be selected which were considered worthy of national acceptance; and that being done, he made them over by a deed of gift, dated December the 22nd, 1847, to the Trustees of the National Gallery. The collection so transferred comprised 157 pictures, all but two by British artists, and all of the highest proportion by living artists. The pictures having been selected in the first instance for a private residence of moderate dimensions, are mostly of cabinet size, and to a considerable extent of homely subjects; but they include favorable specimens of a large proportion of the chief disciples, and of English youth, like Mr. Vernon lived long enough to see that his munificent gift was warmly appreciated by the great bulk of his countrymen; but not to see it provided with a fitting repository. He died May 32nd, 1849. Since his decease the Vernon collections have formed a temporary resting place in Marlborough House. To it has been added the splendid bequest of Mr. Turner (Turrans, J. M. W., S. 2); and Mr. Sheepshanks has also presented to the nation his noble collection of 233 paintings in oil by English artists; but his gift is clogged with stipulations as to the place where they are to be deposited, which prevent them from being—for the present at least—placed along with the Vernon and Turner pictures. It is however greatly to be desired that some arrangement may be made by which these collections may be brought together, and thus form the commencement of a National Collection of British Art worthy of the nation.

A marble bust of Mr. Vernon, purchased by subscription, is placed in the hall at Marlborough House; where also is a marble group by Gibson of Hylas and the Nymphs, and about half a dozen marble busts, presented with his pictures by Mr. Vernon—the somewhat sorry commencement of a National Collection of the works of British Sculptors.

VERTEBRA is the name given to each of the separate bones of which the spinal column of the skeleton of the Mammalia is composed. [Skeleton.] Although in technical anatomy the term is thus restricted, it has recently received a much more extended signification. Professor Owen defines a vertebra as "one of those segments of the endo-skeleton which constitute the axis of the body and the protecting canals of the nervous and vascular trunk; such a segment may also support diverging appendages. According to this definition, the vertebra becomes the type or plan on which all the bones of the skeleton of vertebrate animals are constructed. It is not only a portion of the spinal column, but the elementary form to which all the parts of the skeleton may be reduced. The bones of the head, of the thorax, of the pelvis, and the limbs, however complicated, are reducible to the plan of the typical vertebra. In the history of the development of this interesting branch of anatomical inquiry a variety of opinions have been expressed, as to what may be regarded as the most important elements of a typical vertebra, since in no instance do we find all the parts of the vertebra developed in exactly the same manner.

The diagram exhibits a typical vertebra, according to the plan of Professor Owen.

This plan does not include the parts which constitute the diverging appendages. Of this plan Professor Owen says, "The names printed in Roman type signify those parts which are derived, in the same manner, from distinct and independent centres, I have termed 'autogenous' elements. The italic denotes the parts more properly called processes, which shoot out as continuations from some of the preceding elements, and are termed 'exogenous', e.g., the diapophyses, the upper extremity of the transverse process, and the hyopophyses or the 'after-born' or 'artificial processes' of human anatomy."

The autogenous processes generally circumscribe holes about the centrum, which in the chain of vertebras form canals. The most constant and extensive canal is that formed by the centrum and the adjoining portions of the lobed or pedunculated vertebra, and is called the vertebral canal, or spinal canal. This canal communicates with the brain by a passage in the cranium, and with the body of the vertebra by a passage in the spinous process, and in the pedicles. It is bounded by the centrum, and marked C. in the diagram. The second canal is formed by the hemapophyses, and is below the centrum, and embraces the central circulating organs (A), the heart, and the large trunks of the vascular system. At the corresponding level in the lower vertebras, in that region, rise two other canals, formed by the three lateral elements of the vertebrae, and these often embrace an artery and a nerve. Thus a typical or perfect vertebra, with all its processes, has formed a central point of common centre such a vertebra is seen in the thorax of man, and most of the higher forms of vertebrate animals, as in the neck of many birds. In the tails of most reptiles and Mammalia the hemapophyses are articulated or anchored to the under part of the centrum being needed there only for the caudal artery and vein. But where the heart is to be lodged an expansion of the hemal arch takes place, analogous to that which occurs in the neural arches when the nervous trunk arises from these arches. In the vertebrae the lower part of the thorax, spinal column, and skull, may be traced to the elements above referred to, the parts of the two pairs of locomotive organs which all vertebrate animals are endowed may be traced also to the same arches. And the diverging and complexing of all others are most subject to change,—now developed to an enormous extent, and again almost entirely disappearing, according to the necessity of adapting the animal to its special habits. With the exception of the posterior and anterior extremities, these organs of the skull are to a limited degree. It is through the study of these appendages that the pectoral fins are seen to be the homologues of the anterior extremities in the reptiles, of the wings in the Birds, of the flippers of Seals and Whales, and of the limbs in Man. In like manner the abdominal fins of Fishes are the homologues of the legs in Birds, and of the posterior extremities of the Reptiles and Mammalia, and the legs in Man. These homologues include not only the totality of these organs, but the individual parts, and the scapula, clavicle, coracoid process, humerus, radius, ulna, carpal and metacarpal bones, and phalanges, in the higher Mammalia and Man have their homologues in the lower form of vertebrate animals. So well does the creature agree with its illumined place, that the femur, fibula, tibia, tarsal and metatarsal bones, and phalanges.

We have no space here to enter into the details of the application of this general plan to the structure of the skeleton, and this only on the hypothesis that this has been done in a most masterly manner by Professor Owen, in his 'Report on the Homologies of the Vertebrae Skeleton,' published in the 'Transactions of the British Association' for 1846, and also subsequently in an independent volume devoted to the same subject. This department of anatomy, inquiry is no longer a matter of ingenious hypothesis and verbal speculation, but has been placed by this inquirer, through the unerring principles of comparative anatomy and development, upon the firmest basis, and may be regarded as an essential part of scientific truth.

VIC0, FRANCESCO DE, one of the most distinguished astronomers of modern Italy, the son of Count Ascacio de Vico-Ubaldini and the Countess Amalia Archinto, was born at Milan on the 15th of November 1780. He was educated partly at the College degli Nobili in Urbino, partly in the school of the well-known congregation of the Scolopi at Siena, and entered the Jesuit Society as a novice in 1823. After passing with much distinction through the usual stages, both in the classics and in the sciences, he was appointed, in 1830, as professor of the first duties assigned to him was to calculate the time of the appearance of the then expected Halley's comet, both according to the elements of Damoiseau and to those of Pontecoulant. The young astronomer had the satisfaction of being the first to observe the comet, on the 8th of August 1835. Soon afterwards, D'Arca, in consequence of the great age of S. Dumonchel, becoming
the principal astronomer of the Roman observatory, under-
took a long series of observations for the purpose of ascer-
taining the suspected error in the latitude of Rome, as
determined by his illustrious predecessors, Boscovich, Calan-
drelli, Cassini, and Flamsteed. These observations, which
amounted to nearly 8000 in number, were remarkably ac-
curate, and the result was a correction of an error of two
seconds in the received latitude. He engaged at the same
time on a similar series of observations for the longitude, in
connexion with which he would search the heavens for 10, 1847.
Father afterwards, Father De Vico, at the instance of Schumacher
of Altona, undertook a course of observations of the planet
Venus, for which the clearness of the Roman atmosphere
was peculiarly adapted, with a view to the determination of the
perihelion, and that makes as well as the other observations
this undertaking contributed more than all his previous
labors to establish his reputation among the astronomers of
Europe; and his subsequent observations of the satellites of
Saturn, and of the inner ring of that planet, as well as his
detailed reports on the nebulae, which about that time had
become a prominent subject of interest, fully sustained that
reputation.

Father De Vico however is most popularly known as an
observer of the trans-Atlantic discoveries in the
cometary system, which he was one of the earliest in the most
recent times to take up as a systematic study. During the
years 1845, 1846, and 1847 he discovered no less than eight
of these mysterious bodies, in seven of which his claim to
priority was established. He was at once observed by another astronomer two days before it was dis-
covered (independently however) by Father De Vico.

Another more humble but hardly less useful work undertaken
by Father De Vico was the preparation of a new system of astronomical maps and charts, in which he is said
to have made considerable progress; but in this and other
works which he had commenced, he was interrupted by the
Revolution of 1848, by which, in common with the other
members of his order, he was expelled from Rome. He was
thereafter treated with much distinction during his exile by his fellow-
astronomers in France and England, and received more than
one invitation to fix his residence in either of those countries;
but the circumstances of his order at that time determined him
not to accept any of these offers. He continued to entertain
the hope of returning to Italy, and in 1850, at the age of forty-three.

Father De Vico is chiefly known in literature by his contributions to the 'Raccolta Scientifica,' a scientific
journal which owed its origin principally to himself, and
which is still continued under a new form.

[In 'La Vita e ai Lavori del P. Francesco
De Vico, Rome, 1861.]

VICTORIA, ALEXANDRINA, Queen of the United
Kingdom of Great Britain and Ireland. [In the 'Penny
Cyclopedia,' the history of the Kingdom is briefly given
under the names of the respective Sovereigns; and that
history is brought up to the accession of our present Queen.
In this historical point of view, and not as the biography of
a living personage, we continue the series of Monarchs, but upon
somewhat different a plan, as we shall presently explain.]

Queen Victoria, the only child of Edward, Duke of Kent,
the fourth son of George III., and of Maria Louisa Victoria,
a daughter of Francis, Duke of Saxe-Coburg Saalfeld, was
born at Kensington Palace, London, May 24, 1819. The
Duke of Kent had married in 1818, in Paris, Princess
Charlotte of Leiningen, afterwards Princess of Saxe-
Belgium, who was the widow of the Prince of Leiningen, on
whose death in 1814, she had been left the guardian of her
younger sons and the ruler of their territory, both which
duties she fulfilled with remarkable care and success.
The Duke of Kent died on January 23, 1820, leaving his widow
in charge of their infant daughter. On the accession of
Victoria to the throne on June 30, 1837, she found Lord
Melbourne at the head of the government, and she willingly
confided to him many of her private affairs. The Queen
was married to Prince Albert-Franz-August-Karl-
Emmanuel, the second son of Ernst-Anton-Karl-Ludwig,
Duke of Saxe-Coburg-Gotha. On November 21, 1840, the
Princely Royal was born, who was married, January 25,
1846, to a lady of the Roman Catholic Church.

On November 9, 1841, was born Albert Edward, Prince of
Wales: on April 25, 1843, Alice Maud Mary; and on August 6,
1844, Alfred Ernest Albert; on May 25, 1846, Helena
Augusta Victoria; on March 18, 1848, Louisa Caroline
Alberta; on May 1, 1850, Arthur William Patrick Albert;
and on April 7, 1853, Leopold George Duncan Albert; and on
April 14, 1857, Beatrice Mary Victoria Feodora.

We have considered it desirable, in the instance of our
present Queen, to quote from the accounts of all the
previous sovereigns which so completely belong to our own immediate times, to deviate from the
plan which has been pursued in the biographies of the
other English sovereigns. A connected historical sket-
ch of the events of the reign, with an enumeration of opinion;
and we therefore prefer to notice, in the dry form of a
terological abstract, the most prominent circumstances of the
past one and twenty years. The historian of this remarkable
period will point to it as an epoch of unparalleled progress in all
the various arts and sciences, and will be struck with
the steady advance of the most enlarged principles of
political action, without the slightest disturbance of that
respect for law and order, in the absence of which no acces-
sion of freedom could be permanent. He will mark a growth
of industrial prosperity so mighty and so rapid, that it could
only be accomplished by a people living under the stability
of a monarchy and the liberty of a representative government.
He will see the happiest development of the aim at an universal
landslide, so full to be ensured by all the States, but with an accelerated energy at every step, which gives
the hope that the inequalities in the condition of the people
may become far less onerous than in any previous period,
and eventually produce a community more united by com-
mon affection and interest, in which the well-being of the
people will be the cause, and the welfare upon the progress of the civilising Arts—how Music has
again become an enjoyment for all; how Painting has re-
ceived a more important impulse in the extension of taste,
than it ever derived from mere patronage; how the higher
branches of Art have come to the aid of manufactures,
if Literature has become less bold and original, it has
applied itself to the advancement of knowledge and
amusem. of a body of readers, who have increased tenfold since
the death of the Queen Victoria. We cannot open our
pages to record the growth of the domestic virtues; the
universal contempt with which the low indulgences of a former
generation are regarded; and with some differences upon minor
points of doctrine and ceremonial observance, how the great
religious principle which has so disting. Protestant
England prevails throughout the land in companionship
with that spirit of free inquiry, derived from our scientific
progress, from which truth has no reason to shrink. How
large a portion of the great characteristics of our time have
been derived from the influence of the personal character
of Queen Victoria, the future historian will feel it his duty
to set forth. It is impossible for any thinking man, who has
had the happiness to live under her benign rule, not to feel how
sincerely she has endeavoured to contribute to the welfare
of his country. It is a great feature of this reign, that
during seventeen years it was a reign without the excitement
of foreign warfare. A prince with martial propensities
might have been urged by such a country as ours to break
trans-Atlantic quarrels. But let it not be forgotten that,
when the sword was to be drawn in a just cause, a more
animating example was never presented than that derived
from the patriotic spirit of Victoria; and that the world
felt that, after forty years peace, Great Britain, under a
Queen, was as warlike as under the most chivalrous leader,
and far more just and considerate towards other nations,
than in the days when war was held the greatest glory. In
the chronological abstract which follows, will be found
the most interesting events which have come upon the great
characteristics of the reign of this queen. But there are others,
far more numerous, and some more important, which cannot be indicated in such a form.

We shall only attempt to offer an abstract of what
happens when he desires to know the date of some remarkable
occurrence which belongs to the public history of the period.
1837. June 20, Queen Victoria succeeded to the throne,
and was proclaimed on June 21. The Duke of Cumberland
was succeeded by his son, Prince Albert, Duke of Cambridge.
This prince was restricted to males, and thus the connection of
the royal family with the Continent was suspended after continuing for
133 years. July 6, William IV. was buried at Windsor.
November 20, the Queen in person opened the new parlia-
ment, and in an address delivered to both Houses, she
spoke of the war, and of the dangers which threatened the
United States in Canada. December 14, the Canadian rebels were de-
feated at St. Eastace in Lower Canada, their chiefs saving
themselves by flight. December 29, the American United

States steamboat Caroline, which had brought assistance to the rebels, was attacked and burned, on the territories of the United States.

1838. January 5, the Canadian insurgents, under Dr. Mackenzie, surround Toronto, but are repulsed by the governor, Sir Francis Hallow; and a proclamation of the President of the United States forbids the attacks of its citizens on neutral territory. January 10, the American government sells its claims on the British government for $325,000. May 1, the Chartist proclamation and the proclamation of the French government are burnt down. January 16, the Earl of Durham was appointed governor-general of her majesty's possessions in North America, with extraordinary powers, in order to effect a settlement of the difficulties there. May 23, the manufacture of Sir John Siners (which left April 4) and Great Westerns (April 6) steam-ships arrived at New York from England, being the first vessels which crossed the Atlantic by steam power alone. May 31, a junatic named Thom, who assumed the name of Sir John Parn reserved his half kingdom of Jerusalem, having excited a number of deluded followers against the Poor-Law Act, a contest ensued with the military near Gauterbury, and Thom having shot two men himself shot by one of the soldiers. June 20, the coronation of Queen Victoria, attended by Marshal Soult, the old opponent of the Duke of Wellington, as ambassador from the King of the French. July 31, the new Irish Poor Law and the International Copyright Acts were passed. On August 4, he struck the American ships andprechased an Irish Tithe Compositional Acts were passed. August 16, the Queen proclaimed parliament. On September 17, the London and Birmingham Railway was opened throughout its entire length. October 9, the Earl of Durham declared his intention to resign the government of Canada, in consequence of some of his proceedings being disapproved. November 1, the rebels were defeated at Napierville. On November 4, there were riots at Montreal. In November, intelligence was received that Dost-Ahmed Khan, the chief of Kabul, had joined Persia with an intention of attacking the British possessions in India, whereupon the governor-general had adopted the cause of Shah Soojah in his claims on the throne of Afghanistan. [AFGHANISTAN, 5.] November 26, the United States and Russia agreed to co-operate in the same, and the insurrection was wholly suppressed. December 12, a proclamation was issued against illegal Chartist assemblies, several of which had been held at night in various parts of the country, those attending them being armed with guns, pikes, &c.

1839. January 7, the Académie des Sciences at Paris made a report on the invention of M. Daguerre, the originator of the daguerreotype process, which has been found to be of considerable practical importance. The troops of the East India Company occupy Adua. May 6, the government having been defeated in the House of Commons on a bill for suspending the constitution of Jamaica, where the House of Assembly had refused to pass the measures for its complete abolition. September 7, the House of Commons, at the instance of the Lords, on the 7th, that the ministry had resigned. On the 8th, Sir Robert Peel received her Majesty's command to form an administration; but owing to the refusal of the Queen to dismiss the ladies of her household she declined the commission, and on the 10th Lord Melbourne was reinstated. June 8, ratification of the treaty for the separation of Holland from Belgium. June 14, the Designs Copyright Act passed. July 15, Chartist riot at Birmingham suppressed by the military, but not till a large amount of damage had been done. August 17, the Postage Act passed, enacting a uniform rate throughout the kingdom for all letters not exceeding half an ounce in weight, and it gave the Treasury the power of fixing the rate at first, though it was to be ultimately one penny. This was done by reducing all rates above 4d. to that sum, leaving all below 4d. unaltered. It came into operation on December 5; and on January 10, 1840 the uniform half-ounce rate was reduced to one penny. The Act was for one year only, but it was confirmed in 1844. November 4, Newport in Monmouthshire was attacked by a party of Chartists, estimated to number about 10,000 men, under the command of John Frost, an ex-magistrate. They were opposed by the mayor, Mr. Phillips, and a party of special constables, numbering about 200. The rioters broke the windows of houses, fired on the inmates, and the mayor was wounded; upon which the soldiers fired, made a sortie, and dispersed the mob, of whom about twenty were wounded. The next day Frost and some others of the leaders were apprehended; on December 31, they were tried, found guilty of high treason, and sentenced to death, but the punishment was commuted to transportation for life, and in 1856 a free pardon was granted to them. Government papers announce the termination of her hermitage marriage with Prince Albert. November 24, the trade between England and China was stopped by order of Lin, the Chinese imperial commissioner. 1840. January 11, a Chartist outbreak contemplated at Sheffield was quelled, and in Westmorland, some of the leaders being apprehended. Slight disturbances took place about this time also, in a few other towns of the North. January 16, parliament opened by the Queen, and Lord John Russell was again returned for Montreal. Lord Melbourne, who had brought an action against Hanard, the printer to the House, for a libel contained in some of the papers printed by order. He had obtained a verdict, issued execution, and the sheriffs of Middlesex had seized and sold some of Hanard's books. It had been charged that Hanard had sold books that were the subjects of breaches of privilege. At different times, and after considerable discussion, Stockdale, his attorney, the two sheriffs, and some subordinate agents, were committed to the custody of the sergeant-at-arms. A bill was subsequently thrown out, Lord John Russell, for exempting from such actions all papers ordered by the House to be printed, which was passed on April 14. February 10, the marriage of the Queen took place, attended with festivities throughout the country. April 16, the French government of the present year, note, complaining of the establishment of a monopoly of the trade in sulphur granted to a French company, in contravention of the treaties with England. As the Neapolitan government refused satisfaction, an English fleet was ordered to take possession of the island of Naples. November 28, the French government and the United States agreed to prevent all French hostilities, and the sulphur trade restored to its former course. May 6, the new stamps and envelopes for pre-paid letters came into use. June 4, the Act for better effecting The Combination in England and Wales received the royal assent. July 3, the fort of Amoy, in China, was destroyed by the English fleet, and on the 10th, the island of Chusan was taken. July 23, the Act for uniting the provinces of Upper and Lower Canada received the royal assent. September 7, the children to sweep chimneys, and on August 10, that for regulating Irish Municipal Corporations, received the royal assent. August 11, the parliament was prorogued. August 25, the Carlist insurrection in Spain having been suppressed, the Duke of Angouleme, as a mark of respect, visited Paris. December 5, Mehemet Ali, of Egypt, who had been for some time resisting the claims of the Sultan of Turkey to the sovereignty over Egypt, who had invaded and taken possession of the land ledge, was in England and France accepted on this day the terms proposed. Commodore Napier with an English fleet had greatly distinguished himself by his successful attacks on Beyrout and Acre. December 15, the remains of Napoleon Bona parte were deposited in the island of St. Helena; and on the 26th were this day deposited with great ceremony in the Hôtel des Invalides, having been brought to France by a French squadron under Prince de Joinville.

1841. January 9, a meeting of the Repeal Association was held in Dublin, to receive the accounts of the preceding year; and during the sping several monster Repeal meetings were held to hear the addresses of Daniel O'Connell, some of which were attended by as many as 150,000 persons. Jan. 9, the Bogue forts at Canton were attacked and taken by the British forces. January 30, after some further hostilities, the Chinese government proposed terms, by which Hong-Kong was ceded to Great Britain, direct official communications between the two powers granted, some additional ports opened to trade, and an indemnity of six millions of dollars paid. January 26, parliament commenced its sittings. Feb. 10, the union of the Canadas proclaimed at Montreal, and Lord Sydenham took the oath of office. February 15, a dispatch was given to the British consul at London, to celebrate the foundation of the most recent colony of Great Britain—New Zealand. On March 15, at a meeting of the Vice-Chancellor, heads of houses, and proctors, of the University of Oxford, a resolution was passed condemning the Puseyite revival in Oxford. March 21, the annual meeting of the Metropolitan Anti-Corn-Law Association was held, numerous meetings of similar object having been held in various parts of the
country. April 26, a meeting called by the Archbishop of Canterbury, in London, to raise funds for sending out bishops to New Zealand, was held. On the same day, the preliminary expedition of the second colony to New Zealand sailed under the command of Captain Wakefield; the colony to be formed on the principle proposed by E. G. Wakefield, limiting the area, and applying the revenues to the support of the clergy. May 18, a great meeting held at Manchester, to petition for a total repeal of the Corn-Laws. Many other meetings for the same purpose were held throughout the country, some of which were attended by petitions, and corporate for universal suffrage. May 23, hostilities re-commenced at Canton. The British forces, under Sir Hugh Gough, took two forts, and the town capitulated, having agreed to the previous terms and to pay six millions of dollars for the forts. June 27, the case of the seven ministers of the presbytery of Strathkoghe was brought before the assembly of the Scottish Church; when they were suspended for having obeyed the order of the civil courts in placing the minister of Marnoch against the order of the Assembly. A large minority protested, and a numerous meeting was held in Edinburgh on the following Monday (31st), to express their sympathy with the deprived ministers. On the 27th Sir Robert Peel brought forward a resolution in the House of Commons, recommending a tone of moderation and conciliation as well as of firmness and confidence in the discussions with China. June 21, the Act for the Compounding of Copyhold and Customary Tenures, and that for affording Facilities for the Conveyance and Endowments of Sites for Schools received the royal assent. August 9, the new parliament met. An amendment to the address was moved by Sir R. Peel, as an object of the resolutions. After a debate, the amendment was carried. On the 30th, the ministers announced their resignation, and Sir R. Peel was commissioned to form a new ministry. In September, amid increasing agitation and distrust and discontent, the extreme distress of the manufacturing districts of the country, October 4, a great fire occurred in the Tower, which destroyed the storehouses and the small-army arsenal. December 31, Lord Ashburnham was appointed to a special mission to the United States, in order to settle the various differences between the two countries, which he concluded in September 1842.

1842. January 17, the first stone of the new Royal Exchange was laid by Prince Albert. February 6, about 600 depositors of the Bank of England in London, to promote its objects. April 29, a new law for a graduated scale on the importation of foreign corn received the royal assent. May 4, the Boers of Port Natal having threatened to attack the new fort, they were attacked by Captain Smith with a small force, whom they defeat, but were beaten in a second action on June 26, and forced to submit. May 30, John Francis fires a pistol at the Queen, who escaped uninjured; Francis was tried for the attempt at the Old Bailey, found guilty, and sentenced to be hanged, but the punishment was commuted to transportation for life. June 4, there were riots at Cork and Ennis, occasioned by want of food arising from the potato rot in 1841; and great distress and discontent continued to exist among the manufacturing population of England. June 15, the treaty with the Chinese not having been ratified, the British forces entered the river Yang-tse-Kiang, and seized several forts with numerous cannon; and on the 19th they took possession of Shanghai. June 26, Sir Robert Peel's bill imposing an Income Tax of 7d. in the pound on incomes of 150l. a year and upwards received the royal assent. July 9, a deputation from the Anti-Corn-Law Association waited on Sir R. Peel, to represent the extreme distress of the labouring poor. July 10, a petition from the royal assent, proposing a representative government on New South Wales. August 8, a serious riot took place at Manchester owing to the distress, and the riots extended subsequently to other towns in the north. August 26, the Amendment Act received the royal assent. August 29, the visit of Prince Albert visit Scotland. September 30, a special commission was held to try the offenders in the late riots, when fifty-four were convicted, and sentenced to various periods of imprisonment.

1843. January 9, O'Connell announced at a weekly meet-
he proposed to continue the income tax, to repeal all duties on export, to abolish the duties on 430 articles which yielded only a trifling income, also those on cotton-wool, glass, and staves, and to substitute an annual licence for the auction duties; these were ultimately carried. March 6, Sir Robert Peel introduced an act to enable Parliament to establish public offices, which was passed on March 14. May 5, a banquet in aid of the Anti-Corn-Law Association was held in Covent Garden Theatre, by which 25,000l. was realised. On the 22d a meeting was held in London for the establishment of banks, and on the 27th a meeting in the Dublin Coffee House, Cambridge. May 23, the Arctic expedition of discovery, under Sir John Franklin, sailed from Greenhithe, and, unfortunately, never returned. May 25, a terrible fire took place at the new corn exchange at Manchester; the fire destroyed 20,000 persons left destitute; parliament voted 20,000l. for their relief; subscriptions were raised, and collections were made in all the churches, under the authority of the Queen's letter. May 29, a new convention between England and France for the better suppression of the slave trade was signed. June 15, a French and English squadron attacked Madagascar, in consequence of the Queen of Madagascar having threatened the traders of those countries with expulsion: they destroyed some forts and coast settlements, but nothing was accomplished. June 30, Sir R. Peel's Act for the endowment of Maynooth College received the royal assent; and on July 21, the Acts for the establishment of museums in large towns, for the assistance of new colleges in Scotland, and the amendment of the Poor Law in Scotland. October 31, Mr. Waghorn arrived with the East India mail, which he had brought for the first time by the Overland route. During this month the railway mania reached a crisis, and a second great effort was made to establish railways. The Irish Roman Catholic bishops condem the new colleges. November 22, Lord John Russell issues his letter to the electors of London, declaring for a total repeal of the Corn Laws. December 10, it having been previously understood that there had been many discussions in the cabinet on the subject of the Corn Laws, it was made known that ministers had resigned, and that Lord John Russell had been sent for to form a ministry. On the 20th, he having failed, Sir R. Peel's bill was introduced for, and re-accepted on the 16th. 1846. January 3, the corporations of London and Dublin presented addresses to the Queen representing the sufferings caused in Ireland by the potato-rot of the previous year. January 6, a meeting of agricultural labourers was held at Wootton Bassett in Wilts, at which they petitioned for the abolition of the Corn Laws. January 11, the New Zealand chiefs, who had previously committed several outrages on the British settlements, were attacked and defeated: on the 14th, the native commission was opened by the Queen, who referred to the failure of the potato crop, and recommended the consideration of the propriety of relaxing protective duties. On the 27th Sir R. Peel announced his intended repeal of the Corn Laws. May 3, an act was passed for raising a treasury order was issued allowing the importation of Indian corn, rice, and buckwheat, at a nominal duty of one shilling per quarter. April 4, the governor of the Cape of Good Hope commenced a war upon the Caffres, who had been committing depredations on the colonists. June 9, the town of St. John's, Newfoundland, was destroyed by fire; the damage done amounted to 1,000,000l. June 12, a treaty with the United States for the settlement of the Oregon boundary was signed by the American and British ministers. On the 26th the Corn Duties Repeal Act, and the Customs Duties Act, which gave great freedom to commerce, received the royal assent. On the same day, on the motion for the second reading of the Prevention of Wife Bill (a coercive measure for Ireland), the minister were defeated, and immediately resigned. On June 7, Lord John Russell and other members of the new ministry were sworn into office. July 28, W. S. O'Brien and many others seceded from the Repeal Association, and on the 1st of September, the Glasgow police were ordered to obtain their object by physical force. August 26, an Act for the establishment of Public Baths and Washhouses received the royal assent, and also the Act for establishing County Councils. September 4, forty-four districts in Ireland were declared by proclamation to the possession of the local authorities, and the provisions of the Labour Rate Act were directed to be put in operation in them. September 14, a formal protest was made by the British government against the marriage of the Duke de Montpensier, a son of the King of the French, with the sister of the Queen of Spain. October 2, the distress in Ireland continuing, and the provisions of the Labour Rate Act proving worse than useless, the lord lieutenant issued a circular authorising the undertaking of works of permanent utility, at the charge of the parish, for the benefit of the poor. October 18, a meeting was held in Edinburgh to consider as to the best means of relieving the distress in the Highlands and Islands of Scotland, where 350,000 persons were without the means of subsistence. 1847. January 2, the British Association established, by which large sums were raised by subscription for the relief of the distresses in Ireland and Scotland. In both of which countries the distress was amounting to a state of famine. October 6, parliament was opened by the Queen, who directed the attention of the Houses to the great distress prevailing, and called on them to provide measures for its relief. May 13, Daniel O'Connell died at Genoa, while on his way to Rome. June 8, the new Irish Poor Law Bill received the royal assent; on the 21st, that for the improvement of towns; and on the 23rd parliament was prorogued. October 17, thanksgivings were offered up in all the churches for an abundant harvest. October 25, in consequence of a great monetary excitement, the temporary suspension of Sir R. Peel's Bank Restriction Act was ordered, and the order was withdrawn November 23. November 18, parliament re-assembled, and passed an Act for the suppression of crime and outrage in Ireland. 1848. February 21, the revolution commenced in Paris by which Louis Philippe ceased to be King of the French. On the 24th the king abdicated. On the 26th the republic was proclaimed. Louis Philippe and his family fled, and Prince Louis Napoleon arrived in Paris. February 24, the proposed great Chartist demonstration on Kennington Common, near London. The government however had appointed special constables; an intended procession was prevented, and the affair passed off without a struggle; on May 31, the state trials in Ireland commenced; the jury could not agree in a verdict as to Mr. O'Brien and Mr. Meagher. Mitchell was tried on May 28 for seditious writing in the 'United Irishman,' found guilty, and sentenced to fourteen years' transportation. July 23, in a judgement took place between the Government and the government forces at Ballingary: the rebels were easily defeated. On August 5, W. S. O'Brien was captured, and on the 19th Meagher, O'Donohoe, and Lyne. August 20, twenty Charter leaders were arrested. August 29, Sir H. Smith defeated the rebels under Pretorius at Bleom Platts, in the Cape of Good Hope colony. August 31, the Health of Towns Act received the royal assent. September 30, the Chartist trials were concluded in London; the greater part were sentenced to transportation for life. October 9, the trial of the Irish rebels concluded, and O'Brien, Meagher, O'Donohoe, and M'Maus were sentenced to death. 1849. During this year the Hungarian insurrection against Austria, which took place in Hungary in Germany succeeded the revolution in France of 1848, but Great Britain took no part in these commotions. May 11, on the appeal of Smith O'Brien and others to the House of Lords the judgment was confirmed, and on July 9, they were all transported. On May 13 a large meeting was held at Cape Town to protest against the attempt to make the Cape a penal settlement, and the efforts made were ultimately successful. On June 28, the Act for repealing the Navigation Laws received the royal assent. On July 5, the Chartist Relief and Repeal Act. In August a report was furnished to the Cabinet at Washington by Colonel Mason, confirming the discovery of vast quantities of gold in California. On September 16, prayers were offered up in the churches for the removal of cholera. December, 1848, the agreement of the Russians to place the fleet that entered the Dardanelles. December 1, the Dowager Queen Adelaide died. December 18, a large assemblage of tenant farmers and cottiers took place at Mullinalhine in Tipperary to petition for Tenant Right. December 24, the Privy Council and Investigator leave Woolwich in search of Sir John Franklin. January 25, a meeting held in the Mansion House, London, in furtherance of the Industrial Exhibition of all nations. July 30, Baron
Rothschild, having been elected for the city of London, attended the House in order to take his seat, but was refused because he objected to take the oaths on the faith of a Christian. August 5, the Act for regulating metropolitan inter- motions, being under the Royal assent, as also an Act for the better government of the Austra- lian colonies, forming Victoria into a separate colony, and giving it a representative legislature. August 16, the Act enabling the Church of England in Scotland to receive the Royal assent, and making the prelates of the Church of England resident in Scotland subject to conviction in England, was passed. August 21, the Queen embarked at Osborne to visit the King of the Belgians. September 24, the pope issued a bull establishing a Roman Catholic hierarchy in England, which, on its promulgation, occurred on November 6, the Catholic ministry resigned, the government, in the interest of the nation, was formed by Charles James Thiers, discovered the North-West Passage by Prince of Wales's Strait. The ship was subsequently frozen up, and the crew were not rescued till April 1853, when they made their way over the ice to Cleveland. November 28, a meeting of the clergy of the Established Church was held at Oxford to protest against the pope's bull, which was followed by public addresses for the same purpose to the Queen from various parts of the country. December 31, Sir Harry Smith, governor of the Cape of Good Hope, declared war against the Caffres. He had been attacked by them and narrowly escaped on the preceding day, and the Caffres defeated our troops in several places.

1851. January 27, Earl Grey in a despatch places the Crimea under Russia, received the legislature of Canada. February 4, Parliament opened, and the Queen alluded to the Ecclesiastical Titles bill, as occasioned by the pope's recent bull. February 22, the Russell ministry resigned, in consequence, as stated, the Queen appointed Mr. Disraeli's motion in favour of agricultural protection, and of Mr. Locke King having carried a motion against them in favour of the extension of the county franchise. On the recommendation of the Duke of Wellington, the Duke of York, the Duke of Marcurt, and the Duke of Kent, were appointed in their places on March 3, May 1, the Great Exhibition of the Industry of all Nations in Hyde Park was opened by the Queen. May 22, the governor of New South Wales issued a proclamation for the search for gold in the newly discovered gold regions without a license. By the beginning of June 20,000 persons were employing themselves at the diggings. August 1, the royal assent was given to the Ecclesiastical Titles Assumption and the New Metropolitan Cattle Market Acts. October 23, Kowath arrived at Southampton, on the 30th he went in procession to the Guildhall of Lon- don, where an address from the city was presented to him. November 6, the Caffres defeated a British force at Water- kloof. December 2, the Prince-President of France dissolved the Lower House. December 28, Mr. Thiers, and others, and on January 2, 1852, his continued authority was voted by 7,430,916 votes against 640,737.

1852. January 1, the Roman Catholic synod of Thieres prohibited the Roman Catholic clergy of Thieres from conducting the Missions in which the Queen's colliege in Ireland. February 3, the parliament met; on the 90th the ministry were beaten on the Local Militia Bill, and on the 23rd they resigned; they were succeeded by one under the presidency of the Earl of Derby, who, on announcing his acceptance of office on the 27th, deprecated the attempts which were being made to produce a panic-fee of invasion by the French. April 13, Major-General Cathcart, who had superseded Sir H. Smith as governor of the Cape, issued a proclamation prohibiting the descent of Prince of Wales on the Vaal river. June 2, the electric telegraph between England and Ireland opened for communication. June 2, the independence of Greystown was guaranteed by the English and American governmets. June 20, the Act granting a representative constitution to New Zealand received the royal assent. July 1, the parliament was dissolved. July 3, a great Tenant—Right meeting at Waringstown in Ireland, at which Mr. S. Crawford, M.P., attended, was dispersed by the magistrates. November 2, a great railway meeting at Manchester, attended by 3000 persons. November 23, three ships arrived in the Thames with a large quantity of Australian gold. December 16, in the new parliament which had succeeded the old, the metropolitan, in fact, had a majority of the budget by 305 against 286; they immediately resigned; and on the 27th the Earl of Aberdeen announced that he had accepted office, and formed a new ministry.

1853. January 6, the Emperor of China legalized the importation of opium, in order to make it contribute to the revenue. March 9, a treaty with the Caffre chiefs was con- cluded by General Cathcart at King William's Town. May 3, Prince Mengezoff presented the Russian ultimatum to the Turkish government, claiming for the czar the protectorate over the Great Khan. May 29, the Russian commissioners were received, and war was rejected. May 12, the Industrial Exhibition opened at Dublin. June 26, the Emperor of Russia issued a manifesto against Turkey, and announced the march of Russian armies against the Crimea. June 29, the Queen reviewed the army at Kertch. October 14, the French and English fleets entered the Bosphorus. December 5, a protocol was signed at Vienna by France, England, Austria, and Turkey, for the maintenance of the integrity of the Turkish empire. December 19, Lord John Russell opened the House of Commons his new Reform Bill, which was aban- doned on April 11, in consequence of the state of public business. February 20, the Grenadier and Coldstream guards embarked at Southampton for Turkey, and other troops followed in rapid succession. March 11, the Queen reviewed a fleet at Spithead previous to its sailing for the Baltic. March 28, war declared by England against Russia. April 22, Odessa bombarded by the French and English fleets. June 7, a treaty concluded at Washington for facili- tating the intercourse of the British North American colonies with the United States. June 8, the Crystal Palace at Sydenham opened by Queen Victoria. June 16, the Act for doubling the income tax, on account of the war with Russia, was passed. June 19, the Act for regulating Oxford University received the royal assent.

1854. August 16, Bomarosu was surrendered to the allied fleet. September 14, the allied army landed in the Crimea, after suffering a very severe action on landing and the preceding month. On the 15th the Russians evacuated Moldavia, and the Daunhian Provinces were garrisoned by the Austrians. On the 20th the battle of the Alma took place, and the Russians were defeated. [RAGLAN, LORD, S. J. SAINTELIAMN, MARTIN, E. W. S.] On November 9, the Third of Seoshtsomm commenced. November 5, the battle of Inkermann, when the Russians were again beaten. On the 14th a violent storm destroyed many ships laden with stores, and caused great calamities on shore. This was followed by a season of great suffering; the roads were impassable; the weather was bitterly cold; men and horses, ill supplied with food or shelter, perished in large numbers, while medical attendance and hospital accommodation were woefully defi- cient. Great dissatisfaction was expressed at the terms, and private subscriptions to a large amount were raised to alleviate the distress. Miss Nightingale organised a staff of nurses, and proceeded with them to Constantinople to super- intend the hospitals, and attend the sick and wounded.

1855. January 11, the Grand fleet of the United Potentates of England, France, Austria, and Russia, were opened at Vienna. Lord John Russell was the English plenipo- tentiary, and his conduct in supporting the propositions of his Russian and Austrian colleagues, was the subject of parliamentary discussion on July 6, and led to his secession from office on July 13. January 10, Sardinia joined the allies, and undertook to send troops to the Crimea. January 29, Mr. Roebuck's motion for a committee to investigate the causes of the sufferings of the army in the Crimea was carried against the ministry by 305 to 145. In consequence the Aberdeen ministry resigned, and on February 10 was suc- ceeded by one of which Lord Palmerston was the Premier. March 2, Nicholas, Emperor of Russia, died, and was suc- ceeded by his brother, Emperor Wladimir. March 15, Poland, by the allies, whose fleets swept the sea of Azooff, and destroyed several towns and a vast number of vessels. June 16, the French attacked the Malakhof and the English the Redan, but were repulsed. July 1, a large assembly of persons took place in Hyde Park to protest against Lord R. Grosemer's Sunday Trading Bill, and some rioting occurred. The bill was withdrawn on the next day, but the meetings and the riots were continued on the two following Sundays. July 12, the Malakhof was bombarded by the allied fleets. August 14, the Metropolis Local Management Act, constituting a representative board for the management of the improvements of the whole of the royal palaces, was carried. August 17, the French captured the Malakhof, and in the night the Russians evacuated the south side of Seoshtom, of which the allies took possession. September 20, the Russians assaulted Kars, and were repulsed by the Turks, assisted by Sir V. F. Williams, several other English officers, and General Keme. Oc-
ber 17, Kiburn, at the mouth of the Dnieper, surrendered to the allies, and on the next day the Russians blew up the fortress of Otsakooff. November 26, Kara was surrendered to the Russians, after a gallant defence; Sir W. F. Williams and the English officers were made prisoners, and treated with great kindness by the Russians. November 30, the King of Sardinia arrived at Windsor Castle on a visit to the Queen. December 19, the united kingdom of Sweden and Norway joined the alliance of the Western Powers.

1857. September 11. The Queen, at the opening of the session of parliament, announced the acceptance by Russia of the terms proposed for a general peace. February 1, Mr. Murray, the British minister to the Persian court, quitted Tehran in consequence of the termination of the war by Russia. February 7, the Queen, having created Sir J. Erskine, Bart., a baronet of the Exchequer Court, a peer for life only, a motion to refer the subject to a committee of privileges was carried against the ministers. The committee reported that such a peerage gave no right to sit in parliament, which was confirmed by the House. Ultimately ministers gave way, and Baron Wenealydav was created a peer in the usual form. April 29, official proclamation made of the peace with Russia. May 25, public celebration of the conclusion of peace. June 10, commercial relations were re-established with Denmark, Edinburgh, and Dublin, and a general illumination took place. July 12, the allies evacuated the Crimia. July 29, the Act for establishing reformatory and industrial schools for criminals, obtained their second reading. August 20, the Queen of Ouds, a successor to the Nautch King, declared against the annexation of her son's dominions to the British possessions in India. September 4, the Royal British Bank stopped payment; on the accounts being investigated gross frauds were returned. September 28, the foreign commercial residents withdrew. November 10, in consequence of the Persians having taken Herat, in violation of a treaty, war was proclaimed at Bombay against that country. December 11, the collection of pictures belonging to Mr. John Sheepshanks was made over by him to the government as a gift to the nation.

1857. March 3, the ministry were defeated on a motion by Mr. Cobden, involving censure on them for the action on Canton. Lord Palmerston then announced his intention of appealing to the country for the continuance of the peace. The business of the House could be got through. Parliament was dissolved on March 21, and a new one summoned, which met on April 30. In a new election the most remarkable fact was the elevation of Mr. Cobden to a seat in parliament, which he called the "Peace Party," failed in getting returned. March 14, the treaty with Denmark for the abolition of the Sound Dues was signed at Copenhagen. An indemnity was to be paid to Denmark, of which England's share was settled at £300,000, and the dues ceased from April 1. May 5, the Art Treasures Exhibition was opened at Manchester by the Queen and Prince Albert. May 7, a mutiny broke out in the Indian army. [See Indian Empire, S. 2.] May 25 and 27, Oudh, one of the British naval forces, attacked a number of Chinese junks in Escabar Creek, and another attack was made on those assembled in Fathakan Creek, in the Canton river. Both attacks were successful, numerous junks were destroyed, a quantity of cannon taken, and a large part of the eneised force killed. The issue of this war, with the capture of Canton, will be found under CHINA, S. 2. June 20, an order in Council directed that in future Prince Albert was to be prayed for in the churches on the Prince Consort. July 10, the Oatham Bill, by which Jews were to be admitted to the House of Lords, was rejected in the House of Lords, after being carried in the Commons by a large majority. In November (chiefly in consequence of a commercial panic in the United States of America), the states of the bank suspended payment, and bankruptcies to the amount of fifty millions were declared. A gold panic occurred in Great Britain. Several extensive failures of commercial houses in London, Liverpool, Glasgow, and other towns followed. Two banks in Glasgow suspended payment, one of them in a state of hopeless insolvency, accompanied with the disclosure of imprudent management in discounting an enormous amount of accommodation bills. As early as October 8 the Bank of England raised its rate of discount to 6 per cent, which was increased to 7 per cent, on the 19th to 8 per cent., on November 5 to 9 per cent., and on November 9 to 10 per cent. On the 18th the operation of Sir R. Peel's Bank Restriction Act was suspended for the second time, and the Bank of England was ordered to issue an additional amount not exceeding two millions, for which an Act of Indemnity was passed on December 19. This calmed the panic, confidence was restored, the rate of discount was rapidly lowered, so on December 31st the bank raised the bullion in the bank increased from 6,666,000l. on November 11, 1857, to 17,617,925l. on March 3, 1866. The effects of the failure abroad, however, which had extended to Hamburg, and most other of the commercial towns of Europe, had most calamitous influences on the manufacturing industry of the country.

On January 14, 1866, an atrocious attempt was made to assassinate the Emperor of the French, by casting explosive balls among the crowd assembled to see him and the Empress pass in procession from the Tuileries to the Luxembourg. The assassination of O'Malley and Gomes were apprehended; and on its appearing that they had recently left England, where each had resided for various but not very lengthened periods, an outcry was raised in France against England, and a petition was presented by the French ambassador, which was published in the 'Moniteur," complaining of the defective state of the law in England respecting conspiracy, and asserting that in England it was allowed openly to advocate regicide. The Earl of Derby brought in a bill to stop this; and that he had undertaken the formation of a new ministry. This was accomplished, and the ministry was completed, and met the Houses on the 12th of March. The new cabinet abandoned the conspiracy bill, but continued the prosecution of Mr. Berkeley, for the ascpected complicity in the conspiracy against the Emperor's life. He was indicted as accessory to the murder of one of the individuals who perished from the explosion of the grenade thrown at the Emperor on January 14, but was acquitted on Sunday April 17, after a trial lasting 3 days, and during which 62 witnesses were called. CHINA, S. 2 almost ceased; and since the reduction of Lucknow [INDIAN EMPIRE, S. 2], the chief military operations have been the taking of detached forts or towns, and the pursuit and capturing of the Chinese, who have been many times driven out of the country. The new Chancellor of the Exchequer (Mr. Disraeli) introduced a budget, in which he announced the reduction of the income tax to 5d. in the pound, the equalisation of the duty on Irish distilled spirits with that of England and Scotland, and the imposition of a penny stamp on every cheque issued, for payment on a banker, all of which were subsequently agreed to.

On April 12 the Oatham Bill was again carried in the House of Commons, but was rejected in the Lords, so far as regarded the clause relieving the Jews. On May 14 Mr. Peel brought in a new bill for having made public a despatch from Lord Ellenborough, as President of the Board of Control, to Viscount Canning, Governor-General of India, condemning the proclamation issued by him. Lord Ellenborough explained the decision of the ministry, disapproved of the publication, Lord Ellenborough rested his case after several nights' debate in the House of Commons the motion was withdrawn on May 21.

VICTORIA, or PORT PHILLIP, a British colony in Australia, is situated on the western side of the continent, extends between [34° and 39° S. lat., 141° and 150° E. long.; and is bounded N. and E. by New South Wales, from which it is divided by the river Murray, and a line drawn from the head waters of that river to Cape Howe. W. by Victoria Gulf, and S. by the sea and the coast of Australia, from which it is separated by the meridian of 141° E. long. The form of the province is triangular, its greatest length being east to west about 800 miles; its
greatest breadth about 300 miles. The area is 86,000 square miles or nearly 63,000,000 acres. The population in 1846 was 32,900; on March 2nd 1851 it was 77,545; on December 1, 1852, the population was 121,127; in February 1856, Bradshaw's "Monthly Guide to Victoria," gave the total population as 430,650, including 33,285 Chinese and 17,680 aborigines. In 1855 it was estimated that the population of the gold-fields of the Victoria colony was 145,582 of which 20,546 were Chinese; in this number there were 3 women, and 3 children.

From Cape Howe, at the eastern extremity of the province, a line of coast, called the Long Beach, extends 200 miles, in a south-easterly direction. This part of the coast, which curves slightly inwards, consists for the most part of low and sandy shores backed by hills. Near the centre are several lagoons, and a considerable sheet of water called Lake Wellington. A short distance from the shore there runs a broad sand, with the exception of Warrnambool and Port Fairy, small harbours for coasting vessels. During the summer the south-easterly winds blow on this coast for three months with great force. From Wilson's Promontory to Western Port the coast is mostly high. From Western Port to the western boundary-line it is generally low. The low shores are sandy, except at some places where swamps exist. West of Cape Nelson the coast is bounded by sand-hills.

Western Port affords good anchorage for vessels of considerable size, and suits the other principal ports of the southern and south-eastern winds by Philip Island, which lies across its entrance. Port Phillip, situated at the western entrance of Bass Strait, is a harbour of great capacity. It is entered by a passage of hills and a half wide, bounded by Cape Nelson on the east, and Cape Lonsdale on the west. The channel is still further narrowed by some shoals which front the entrance. Within, the basin extends about 40 miles north and south, and midway attains the same breadth, seeming to have been formed by the collision of two ridges of Geelong. Hobson's Bay, at the northern extremity of the basin, affords good anchorage for vessels of all sizes, and forms the port of Melbourne. Lighter vessels ascend the Yarra-Yarra 8 miles to the capital, which is only a mile and a half from the sea, in height of 12 feet above the lowest low tide. A breach, 26 miles from east to west, and 10 miles from north to south, has good anchorage on its western shore in from 4 to 6 fathoms; but it is open to the south-east winds, and during the south-west gales a swell sets in, causing a heavy surf on the beach.

Wilson's Promontory, the most southern headland of Australia, is formed by a mountain, which is visible at the distance of 15 leagues. This rocky mass may be considered as the commencement of the Australian Alps, a range of mountains which, for a distance exceeding 70 miles, runs to the west of the north, and farther on, for about 100 miles, to the east of the north, until it approaches 37° S. Lat. From this part of the range, which has a mean elevation of 2000 feet above the level of the sea, there are extending towards the north and east and west. The accessibility both on the east and west are gentle, and are partially overgrown with forests, containing many timber-trees, mostly blue gum and black butt. Near 37° S. Lat., the range above the snow-line, and the portion of it is called the Ajuk Mountains. The valleys in this district comprise much land no less fit for cultivation than for pasture. That portion of the province which from the Point de l'est to the southern portion of the Australian Alps and the mountainous peninsula called Gippsland, extends along the coast to 148° E., longitude, consists of an inclined plane, which however near the mountains appears to descend with great rapidity, as in the middle of the region the plains only 250 feet above the sea-level. The northern portion of this country is traversed by several ranges of hills, which are of considerable elevation near the principal range, but grow lower as they proceed southward. The valleys exhibit a considerable degree of fertility, and the small towns are generally situated in them. In the centre of Gippsland are plains of considerable extent, which are covered with open forests, and are capable of maintaining numerous herds of cattle. The most southern part of the province is traversed by the central off-shoots of the Southern Australian Alps, which are covered with blue, green, and black butt, in which numerous timber-trees are found. The whole of Gippsland is abundantly watered by several streams. The country extending north-east of the province of New South Wales has been but partially explored.

On the north of Port Phillip the watered coast between the rivers falling into the Southern Sea and the Murray occurs about 45 miles from the northern extremity of the harbour, but farther to the west it is between 90 and 100 miles from the sea-shore. On both sides of the watershed the country is hilly and broken, and between 142° and 143° E. long. it rises into mountains. This hilly tract is in general from 30 to 40 miles across. To the north of it is an extensive plain, which descends gently to the sea-shore. Near the sea it is almost level or slightly undulating; but farther north it contains a rather large number of hills, rising from 500 to 700 feet above their bases; among them is Mount Buninyong, the highest peak of which is 3700 ft.; its southern slopes are overrun by lakes which are scattered over this plain, one of which, called Carangamite, is about 90 miles in circumference. Its waters are salt, as are those of nearly all the others. The isolated hills or mountains that appear, from their formation, to be of volcanic origin. This hilly tract contains extensive tracts of the finest land for pasture and tillage. West of the river Hopkins (142° 49' E. long) the land along the sea-shore, as far as Port Bay, is generally poor, and that lying west of that place is still more indifferend. But that portion of the plain which lies north of 36° S. lat. contains a large portion of good land. In some parts it is overgrown with thick forests of Eucalyptus trees, Bignonia, Cassowaria, and other trees peculiar to Australia; they are liberally watered by streams, which are generally free from grass. The numerous hills are thickly wooded, and the best soil is found at their bases.

Of the western division of the province, which, for its beauty and apparent fertility, is called by Sir Thomas Mitchell, who first explored it, Australian Holland. The best portion is that which lies within the hilly tract on both sides of the watershed. Nearly all the ridges by which this tract is overtopped run nearly at right angles to the watershed. The principal of these ridges is one of the most western of the mountainous extremity, and has been called the Grampians. Nearly in the centre of the Grampians stands Mount To-oil, or Mount William, which rises to 4600 feet above the sea-level. Mount Abrupt is 1700 feet, and Mount Sturgeon is 1071 feet. Above these, the sandy and undulating land, which consists of many ranges, with a mean elevation of about 200 feet above the sea, is generally covered with thick timber and pasture.

The country which is drained by the rivers originating in the central and western portion of the Grampians appears to be the most fertile tract of New South Wales. It is abundantly watered by the Nangeela, or Olneya, and its tributaries. The soil is black and rich, several feet deep, and rests on a subsoil of clay. The surface of the higher portion of this plain is strongly undulating, and on it are found many small sandhills.

The hilly tract of the watered east of the Grampians has its surface diversified by numerous narrow ridges of rocks, several round hills of moderate elevation, and many rather narrow valleys traversed by clear and beautiful streams. In some parts it is overgrown with thick forests, in places free from wood, but overgrown with grass to the top. About 30 miles east of the Grampians, some more elevated ridges traverse the watershed. They have been named Pyrenees, but the natives call them the Black Hills. They consist wholly of granite, but are all grassy to their summits, and very thinly wooded. East of the Pyrenees the country more is broken and the hills are higher. There are forests chiefly composed of box and lofty blue gum trees. A considerable portion of the soil is sandy, and the country is covered with extensive forests of fine tall timber-trees of Eucalypti. The country which is drained by the rivers originating in the southern and western portion of the Grampians appears to be the most fertile tract of New South Wales. It is abundantly watered by the Wangeda, or Ogilvy, and its tributaries. The soil is black and rich, several feet deep, and rests on a subsoil of clay. The surface of the higher portion of this plain is strongly undulating, and on it are found many small sandhills.

Between the hilly region of the watershed on the south, the mountainous region of the Australian Alps on the south-east, and the course of the Murray on the north, and the boundary
line of South Australia on the west, lie the plains of the Murray River. The Murray and its tributary the Bayungu flow in wide bottoms, sometimes 8 or 10 miles across, which bottoms are overgrown by high trees, partly swampy or covered with reeds, but having an exquisite degree of fertility in the vigour of their vegetation. In some places are found salt lakes in considerable numbers, but in general the plains are open, grassy, and beautifully diversified with patches of芦苇 clumps of reeds. Even at a con-

siderable distance from the Murray the water is scarce, as there are numerous hollows in the plains, which generally contain water. The plains of the Murray are fit both for cultivation and rearing of cattle. The river Murray, rising many miles above Ballarat, flows in a line along the boundary of the province, entering South Australia at 34° S. lat., after a course of above 600 miles. In the lower part of its course along the border it has a channel 300 yards broad, with a depth of from 12 to 20 feet. Its chief tributaries, which drain the northern division of the colony, are the Mitta-Mitta, Ovens, Goulburn, Campaspe, and Loddon, most of which are dried up during summer and converted into chains of ponds. The Mitta-Mitta rises in the Australian Alps, not far from Lake Omeo, the neigh-

bourhood of which forms one of the gold-fields of Victoria. The Loddon rises near Mount Alexander, the principal gold-field, and its feeders, after the rainy season, are employed in the process of gold-washing. The Avoca, Avon, and Wim-mera, also tributaries of the Pigmy and Grampians chains. The Glenelg, collecting several tributaries from the western slopes of the Grampians, flows southward along the frontier, and enters South Australia just before reaching the ocean. It is in the several affluents, water the country south from the Pyrenees, reaching the sea on a little to the eastward of Port Fairy. The Barwon, after flowing in a north-easterly direction to the neighbourhood of Geelong, bends to the south-east, and falls into the sea near the entrance of Port Phillip. The Yarra-Yarra, a considerable stream, which washes the capital, is subject to heavy floods during the rainy season. It comes in from the mountains to the east of Melbourne and continues in a very circuitous course to the mouth of Port Phillip. It is navigable to the city for small vessels and steamers of light draught. The Latrobe, rising in the Great Swamp, which is divided from Western Port by a belt of land a few miles broad, intersects the southern range of the Alps and flows eastward through Gipps-

land into Lake Wellington. Lake King collects the waters of the Tambo, the Riley, and the M'Arthur, which drain the northern district of Gippsland.

The predominating rocks in the higher masses of the Aus-
tralian Alps are granite, schist, and quartz, intermingled occasionally with sandstone and breccia. These rocks are thrown into si-

aty texture. Quartz, ironstone, sandstone, and clay-slate are general throughout the other hilly portions of the colony. Veins of coal have been found on the coast between Port Philip and the Yarra-Yarra. The Yarra-Yarra, besides lead and mangan-

eese. Rich veins of copper ore have been discovered in the banks of the Yarra-Yarra. The chief mineral however is gold, the discovery of which in 1851 has led to a remarkable increase in the wealth and population of the colony. The gold is found chiefly at Ballarat, 40 miles N.N.W. from Geelong; at Mount Alexander, 76 miles N.W. from Mel-
bourne; and around Lake Omeo, in the Australian Alps. At Ballarat, where the precious metal is found extensively on the margin of the pondage in the season of watercourses, a section of the workings exhibits the following strata:—Red ferruginous earth and gravel, streaked yellowish and red clay, quartz gravels of moderate size, large quartz pebbles and boulders with masses of ironstone set in very compact clay, blue- and white-clay and pipe-clay. The gold is uniformly found in the formations superior in position to the pipe-clay. The richest deposits occur in the blue-clay, where the ore is for the most part quite pure. It is washed from these beds in large Konis of water, and the gold is found in fused pieces of pure native gold, occasionally with quartz-pebbles, and occasionally in rolled water-worn lumps called nuggets. The quantity found has been enor-

mous, and the rush of emigration and others to the diggings was at first proportionate to the production. But the period of activity was but the judicious establishment of a mounted police, and the imposition of a small tax for a licence to dig, reduced the system to great regularity in a short time. The amount of gold exported in 1855 was valued at 10,302,980l. In the early part of 1855 serious riots took place at the gold-
diggings of Ballarat, in consequence of the miners resisting the payment of the licence fees. This led to the substitution of a tax on gold exported from the colony, instead of the licence fee for diggers.

The climate of Victoria is comparatively mild. The mean temperature of summer is 65°, of winter 48°, of the whole year 57. The atmosphere is so dry and elastic that the baro-

meter is sometimes very intense, is less oppressively hot. The temperature occasionally comes from the north, and in 20 to 30 hours reaches 100°. The thermometer are to an ex-
h-treme heat, but they do not occasion great inconvenience, and they are generally succeeded by a refreshing breeze from the ocean. During June, July, and August, the winter months, water flows through the gold-digging districts. In some localities snow showers fall. In August, 1858, snow fell at Bellarine to the depth of seven feet. The average fall of rain for the year is 30·7 inches. The rapid changes of temperature sometimes 30 degrees in 24 hours, are unfavourable to con-
sumptive patients. Dysentery and a species of opthalmia prevail to some extent in the hottest months. On the whole, the climate is found agreeable and salubrious. To wild animals found in the province are, the dingos, or native dogs; the great grey kangaroo, which abounds in some dis-

tricts; the rock wallaby, or badger; kangaroo rat; opossum; flying squirrel; wild cat; bandicoot; sloth, or Australian bear; and various others. Among its birds are, the bustard, or wild turkey, which on some of the plains appear in co-

siderable numbers; the emu, or Australian policeman; the lyre-bird, or Australian pheasant, which frequents the mountains of Gippsland; black swans, which abound in the neighbourhood of Western Port; the emu; magpie; pe-

can; eagle-knighter; and plow. The variety of fish is remark-
able, and a great number appear in great numbers; summer, and also lizards and other reptiles. The bays and rivers abound with fish. Codfish of a large size are found in the rivers of the northern district. Shoals of herrings appear on the coast in great abundance. Several very important timber-trees are, the red-gum, lightwood, blackwood, pine, tea-tree, she-oak or fun, honey-suckle, and ipe-r-

chuck. The kangaroo apple-tree, the grass-tree, and the que-

dang, which forms a fine preserve, are indigenous. The fruits which have been successfully cultivated are, the plum, quince, nectarine, apricot, pear, apple, mulberry, almond, and fig. Several vineyards have been formed. Vegetables are abundant. The potato, turnip, carrot, ca-

bage, broccoli, and radish, grow in a very enormous size. Indigo and flax are indigenous. The tobacco and castor-oil plats and Indian corn grow luxuriantly. The common cereals are produced in great perfection; wheat is of the finest quality, with a return of from 40 to 50 bushels an acre. The wheat-producing district is on the eastern part of Aus-

tralia for the growth of wheat, Indian corn, and potatoes.

In all parts of the colony there are tracts of the finest arable land. But sheep-farming is the principal pursuit in the province, apart from the recent mining operations, and the expectation is that with the addition of very greatly to this. The settled part of the province, comprising principally the eastern and southern portions, is divided into 34 counties. Melbourne, the capital of the colony, is described under Melbourne, S. & S.; but we may add here that in 1858 the receipts were 654,684l., of which a great part was raised by loan; and the expenditure was 669,772l., of which 291,504l. were expended on public works in the city. There are 8 daily newspapers, 8 bi-weekly, 6 tri-weekly, and 51 weekly new-

spapers. The following is a list of the important places in Melbourne. Most of them are of a large size, extremely well printed, and some of them edited with great ability.

The second town in the colony is Geelong, now an im-

portant shipping port, pleasantly situated on the south-

western shore of Port Phillip, at the head of Corio or Geelong Bay. It is regularly built, well supplied with water, and a steadily advancing in population and trade. Smaller towns ascend to the town, but those of greater burden discharge a very important share of the trade of Port Phillip. The town of Geelong consequent on the gold discoveries is shown by the town revenue in 1851, 1852, and 1854, which show-

thus: 1851—2876d. 4s. 1d.; 1852—10,697l. 16s. 1d.; 1854—

1,874l. 1s. 1d. The gold discoveries have also been of the most in public improvements, a large amount of which has been borrowed by the corporation of Geelong for the purpose carrying out extensive improvements. A railway to Me-

lbourne has been constructed. Near the mouth of the Yar-

on the north-east shore of Port Phillip, are the next village
The town of Portland is built near the western extremity of the bay of the same name. It has a small population, but occupies a considerable space, being built in streets crossing each other at right angles. There are some whaling establishments, and the whaling ships, and the neighbouring districts are shipped at the harbour, which is inconvenient and exposed. Bessoil, an active and thriving town, is situated on Port Fairy, some miles east from Portland. It is the port of a considerable agricultural district. A Presbyterian church, built of stone, replacing a wooden structure, was opened here in the early part of 1855. Ballarat, the seat of the gold-diggings of that name, is described by Mr. William Howitt, who visited the place, as containing a large population, who are settling down into regular habits and are constructing a neat, well-laid out, and commodious town.

The principal towns in Victoria colony, in addition to those already mentioned, are:—Alberton, Avoca, Ballan, Beechworth, Beechworth Central, Benalla, Bega, Benalla North, Berridale, Bowraville, Braddon, Brighten, Bungaree, Burnham, Castlemaine, Cheprow, Colac, Flemington, Kilmore, Kyneton, Mount Alexander, Port Fairy, Prahran, Richmond, Sandhurst, and Wangaratta. Brashaw's "Monthly Guide to Victoria," for Feb. 1858, gives the number of post towns as 147.
VIDOCQ, FRANÇOIS-JULES, the chief of the detective brigade (Brigade de Sûreté), at the prefecture of the Paris police, established in 1812, whatever must be thought of his early life as a thief and inmate of the convict yards, undoubtedly did real service to France, by his active pursuit of the marauders who levy contributions on their neighbours' goods. He was born at Arras, the chief town in the department of the Pas de Calais on the 23rd of July 1776. His father was a baker, and was chosen to supply the local government, during the revolution, with bread, flour, &c. Young François was employed in the business before he was thirteen; but formed acquaintances who led him to pilfer his father's money by means of several artful contrivances. These being detected, the boy began to pilfer the stock, spending the proceeds with his companions at a neighbouring wine shop. A watch was at length set over him; which did not prevent his stealing ten silver forks and spoons, and pleading them. For this offence his father gave him in charge, when he was sent to the House of Correction for a few days. While in confinement he was incited by a young fellow-prisoner to rob his father again, by picking the lock of the till, and taking out the whole contents amounting to 80l. Having divided this money with his accomplice, he left Arras, intending to sail for the United States; but the high price of the passage made him change his mind; and being at Ostend a few days after, he was plundered by a sharper of all his ill-gotten gains.

In this state of destitution, he hired himself to an itinerant showman, who kept a small menagerie. His allotted task consisted at first in sweeping out the cage and the reception room. His master, after promoting him to the rank of tumbler and acrobat, wanted him to play the part of a savage who eats raw flesh and drinks blood. The wretched boy refused to undertake this new character, and was discharged. He next took service with the master of a puppet show; from whom he was passed into the hands of a peregrinating quack-doctor. At length weary of this hard probation of vagrant life, which had lasted two years, the seeming penitent returned home, and a kind old priest prevailed on his father to forgive him and receive him. This was in 1791, in his sixteenth year.

But he was too idle and restless for regular work; so he enlisted (after one or two escapades), in the regiment of Béarnon, and set out for Belgium, then the seat of the new war, between France and Austria. He was present in several actions, and was made a corporal; but, having quarrelled with his drum-major, and challenged him to fight, he deserted to avoid a court martial. He then enlisted in the 11th chasseurs, and fought at the battle of Jena, November 6, 1799. Having distinguished himself at the capture of Louny, under Kellermann, October 20, 1799, and being of unusual stature for his age, he was made a corporal of grenadiers. A day or two after he was recognised as a deserter, when he made his escape to the Austrian outposts. Unwilling however to fight against his own countrymen, he counterfeited illness, and began to teach fencing.

After a short stay with the Austrians, he got back to France, entered the 14th regiment, and then returned to the 11th, being present at several actions, and being wounded three times. One of his wounds obliged him to return to Arras, where in consequence of a quarrel he was denounced to the Revolutionary Tribunal as a 'Médecé,' and thrown into prison. However he was soon after released, owing to the good offices of Mademoiselle Bevaller, the daughter of the notorious Joseph Lébon. He married her in 1793, but they separated almost immediately. The next year he went to Brussels, became a professional gambler, made love to a污染防治er, and repenting of his treachery or fearing punishment for bigamy, just as he was about being married to her, confessed the imposture, was rewarded with a considerable sum of money, and took the diligence for Paris, which he entered for the first time in 1796, at the age of twenty-one.

He had not been in the capital many weeks, before the dangerous society of gamblers, swindlers, and loose women, left him once more penniless; which compelled him to return to the army of the north. Several fresh instances of folly, three imprisonments, and as many escapes, succeeded; after this he was confined in the prison of Douai, where he remained eight months. During his confinement, he was mixed up in a case of forgery, which in his autobiography he tries to explain as an act of inadvertence, rather than of guilt. For this however he was tried, convicted, and sentenced to ten years' penal servitude at the galley. As they conducted him, bound to the chair, he excited a revolt among the convicts, but the attempt to escape having failed, he reached Brest, and remained six years at the bagnio.

In this place he completed his studies of the manners, the crafts, the habits, of every class of thief. Two years before the expiration of his penalty, he contrived to escape from the convict-yard, assumed the name of Duval, and returned to his own neighbourhood, where he became an usher to a school at Ambriecourt, near Lille. He was soon re-captured, and sent to Coulon. From this convict-yard, he was then made what he calls "his finest escape." After this he joined a band of freebooters in the south, who plundered the stage-coaches on the highroads. But these malefactors having detected the branded convict on his shoulder, dismissed him from their company, having first made him swear not to
betray them. He resolved to be revenged; and this incident became the turning-point in his fortune. As he was making for the north, Vidocq, having no passport, was arrested and taken before a magistrate, to whom he offered to give such intelligence as would enable him to surmise his late crimes in the heart of plunder. For this purpose, he applied for a temporary release. But the magistrate demurred. "Suppose, on my way to prison," said Vidocq. "I get away from my keepers, come back to you, and resume my bondage, will you then grant me the proviso of being allowed to give information for my own advantage?" He escaped, and made good his offers to assist justice. This service was followed by others far more considerable. These events took place in 1804, but he continued for several years the slave of his antecedents. In 1806 he went to Paris again under the pretense of examining the plays and the dramas which he had learned during the course of his nomadic life. He became a toy manufacturer, a dealer in hardware, and a tailor; but other thieves, who had known him in prison, and who were well acquainted with his embarrassments, left him no peace: sometimes they wanted money, at others they proposed a good bargain; next it was some plunder to be hid. On one occasion they borrowed his cart, to convey the body of a murdered victim to a place of safety. He gained his freedom, but not without hazard.

In 1809, driven to extremity, Vidocq presented himself before M. Henri, the commissioner of the secret police of Paris, acknowledged his critical condition, and offered to give valuable information in case he might be allowed to come and go as he pleased. Several of these solicitations had been several times renewed, in the midst of which he was once more arrested. On this occasion he was sent to Bicêtre, when M. Henri, interested by his perseverances, and in order to prevent his escape, arranged with him a scheme of which he continued to make by correspondence, at last consented the Minister of Police, Pasquier, who returned a favourable answer, in which Vidocq was instructed to furnish information. His revelations then became so numerous and so important, that M. Henri was authorized to keep the knowledge of them, and to employ them. The qualities he displayed in his new functions soon attracted attention. Few detective officers ever possessed so much presence of mind, keen intelligence, bodily strength, courage, and diligence; besides that facility of slang and language, which is the essence of the vulgar. He made it a point, from the outset of his new vocation, to produce at once the culprit and the proofs of his crime. The receivers of stolen goods found in him a more relentless enemy than the thief. At first he put under surveillance the regular police officers; but in 1813 he was withdrawn from their control, and placed under the order of M. Henri alone. His captures were extraordinary. The famous thief Delporte, and Flard, the robber who afterwards stole the most important MSS. of St. Germain des Pres, were shot and handed over by this secret agent to justice. La Contelle, a sort of St. Giles', infested with the worst vagabonds, was purged; the great brigand, Desnoyers, and thirty-two of his accomplices, were taken. About the same time, the famous brigade of detective police (Brigade de巡宮), directed by Vidocq, was formed, consisting at first only of four men; in 1817 the number rose to twelve; and in 1834, when its complement was full, it contained twenty-eight detectives. "It was with this limited force," says Vidocq, "that I had to watch and look after 1900 returned transported, and issue every year from four to five hundred writs." In the single year 1817, he effected 775 arrests, and 39 seizures of stolen goods. His useful brigade cost but 2000£, a year, of which the greater part was deteriorated to the maintenance of his household. In the term of his official employment, he was the butt of continual charges, suspicions, and open accusations. He was said to take part in every crime, to incite robbers for the sake of arresting his dupes, and to have a share in all the plunder. This caused the enmity of the government, and in 1825 he was superseded in his functions by Lacour, whose antecedents resembled his own. In 1826 he established a paper manufactary at Saint-Mandé; and in 1829 he founded the Sarthe, a weekly and a bi-weekly which he employed to give information of the political agitators of the day, but his vocation was not either permanent or precise. Then, in 1834, he set up an office for information on behalf of Trade and Commerce, the object being to enable the fair trader, when applied to for credit, to ascertain the degree of trust to which his new customer was entitled.

In 1844, stimulated by the success of Eugène Sue's 'Mysteries at Paris,' and certain works of the same questionable character, which had appeared in London, he republished his Mémoires, under the title of 'Les Vrais Mystérieux de Paris.' The morbid taste for notoriety of any kind which then prevailed, induced Vidocq to visit London, and exhibit himself, with many curious articles used by French burglars, in the rooms of the Cosmoarans in Regent Street. But this speculations did not answer his expectations. Soon after he fixed himself in Belgium, where he died in 1850.

VINET, ALEXANDRE-RODOLPHE, was born at Lausanne on the 17th of June 1797. His father, who held an official appointment in his native canton, a man of superior attainments, but a somewhat stern disciplinarian, having himself been a pupil of Pasquier, was a strict adherent of the Calvinistic creed. In his youth, his studies were chiefly directed to theology, to which he had been devoted to the service of the church; but then, as throughout life, literature possessed for him a predominant attraction. But still, so indolently had he laboured in his field, that at the age of twenty he was appointed professor of the French language and literature at the gymnasium of Basel. Two years later, 1819, he was ordained at Lausanne a minister of the protestant church, and the same year he commenced his theological course; but during the ensuing years, took an active and prominent part in the great religious movement or 'reval' which occurred amongst the Swiss protestant churches. Besides various pamphlets which he put forth in connection with this movement, he published a dissertation against an opposition to it, he published in 1826 an elaborate 'Mémoire en faveur de la Liberté des Cultes,' and he gradually came to be regarded as one of the leaders of the evangelical party.

M. Vinet was one of the chief promoters of the new ecclesiastical code, which was finally adopted in 1837, and he was for many years, a powerful instrument in the hands of the religious unionists of Switzerland. But when, in 1841, he was made a member of the ministry of the interior, he resolved to devote himself to the study of literature. In 1897 he published a selection of his essays contributed to it, and other miscellaneous, under the title of 'Essais de Philosophe Moral.' In 1837 Vinet was invited by the authorities to take the chair of the new ecclesiastical code, and he was chosen its delegate for the class of Lausanne and Vévey. He took a part in all the protracted discussions which followed, but he could not bring himself to acquiesce in the decisions of the majority, and, accordingly, upon the promulgation of the new constitution which was to come into operation in 1841, he, at the end of 1840, formally seceded from the national church, and resigned his professorship of theology. His opinions had in fact from the publication of his 'Mémoire en faveur de la Liberté des Cultes' in 1836, been approaching more and more closely towards 'voluntarism,' and from this time he became a decided, and, among French Protestants, perhaps the most distinguished advocate of the entire separation of church and state. His matured views on this subject are to be found in the following work, which he published in 1850, under the title of 'An Essay on the Principle of Personal Religious Conviction, and upon the Separation of Church and State, considered with reference to the Fulfilment of that Duty.' But Vinet was far from being the harsh partisan of extreme measures. Adhering to his own views, he exhibited a wide tolerance of the honest convictions of others, and his later years were spent in preaching peace and brotherly love, and seeking by the amenities of literature to soften the asperities of theological controversy.

His last labour was the elaboration of a constitution for the Free Church of the canton of Vaud, formed by the ministers
who seceded from the establishment in 1845, and which he induced the committee appointed by the Church in 1846 to prepare the constitution, to adopt in its integrity. With the Synod however, in which the ultimate adoption of the constitution was vested, he was less successful, and the matter was left undecided. He died without having seen the necessary plans, and those having met with the emperor's approval, the first stone of the new works was laid on the 25th of July 1852. The operations were pressed forward with the greatest vigour, but Visconti did not live to see his city completed. He died on the 29th of December, 1853, having been struck with apoplexy, which is said to have been brought on, or hastened, by over-exertion and anxiety. Visconti's plans were carried out to their finish under the supervision of the inspector, who was appointed to succeed him, and on the 14th of August, 1857, the vast undertaking was declared finished, and the junction of the Louvre and the Tuilleries was inaugurated with great pomp by the Emperor. Of course in time the new buildings having to be rendered uniform in their elevation with those already existing, there was little room for originality, but it is admitted that Visconti has overcome the difficulties arising from the peculiarity of site, &c., in a most conscientious manner, and that he has by his additions, which while harmonizing with the older portions, are more or less consistent in style, — rendered it one of the most magnificent royal residences in Europe.

VITALITY, a term equivalent to that of Life, and applied to the forces, which are manifested in all animals. It is that principle, that is, plants and animals. 

Linnaeus defined the three kingdoms of nature as follows: — Minerals grow; Plants grow and live; Animals grow, live, and feel. Here the fact of living is made to distinguish between minerals and plants, and the rest of the animal life. It is often assumed to be a set of actions under the controlling influence of vital principle, but, as such a principle has never been demonstrated, it must only be regarded as an assumed cause.

Some writers have supposed that all the phenomena of life may be resolved into the action of chemical and physical forces acting upon special forms of matter, and that in plants and animals are presented the results of chemical and physical activity in forms in which it is not existent in minerals. Coleridge, who has termed his 'Idea of Life,' contends that the collective activities of the material universe is as much a life, and its parts as much entitled to be regarded as living, as a plant in its special organs.

Setting aside however the idea of a vital principle, or confining this term to the force which regulates and produces the specific form in each individual animal or plant, and which is then applicable as well to minerals, there are a certain set of phenomena in plants and animals which the term Vitality may be usefully applied in. It may be thus applied without in any manner assuming the existence of any force independent of those which are known to influence all matter upon the surface of the earth.

Thus, the growth and reproduction of plants should be regarded as a vital expression of the contractibility of the muscular tissue, and the sensibility of the nervous tissue. These processes are called collectively Vital Processes. The force by which cells grow has been called the Organizing Force, the Plasmatic Force, the Assimilative Property, and the Metabolic Property. The contractibility of the muscles has been properly called Muscle-Force, whilst the sensibility of the nerves has been called Nerve-Force.

That these forces are dependent on physical forces is seen in the fact that in case of the plants will not grow without light. Muscles-force and nerve-force are not producible but by the assimilation of materials that have been formed by chemical actions produced by heat and light.

The natural philosopher has demonstrated that electricity, galvanism, and magnetism, are different manifestations of the same force. He has rendered it probable that motion, heat, light, and chemical affinity, are also convertible forces. The physiologist has followed this train of thought, and has endeavored to demonstrate that, whatever is produced by the influence of heat and light upon the carbonic acid and ammonia supplied to the cell of the plant. A certain amount of protein is the expression of a certain amount of chemical change, and this again in decomposition is the...
expression or the amount of vital force, which a part composed of protein will exhibit. Vital phenomena are found to be the expressions of chemical and physical changes, and result in one or other of the physical forces. This view of the nature of vitality does not lead to materialism, as the consciousness of man exists independently of the physical changes which go on in his body, and the character of his mental activity is due to the ever-active changes which go on in his body through the agency of the vital forces. VIVIANACEÆ, Vivianoids, a natural order of Exogenous Plants with free stamens, no disc, albinous seeds, a curved embryo, permanent petals, and a ribbed calyx. The species are herbaceous or half-shrubby plants, with opposite or whorled leaves, without stipules. They are related to Tiltosaceæ and Tropoeolaceæ. All the species inhabit Chili and South Brazil. There are 4 genera and 10 species.

VOGEL, DR. CARL, born at Leipzig, in Saxony, in 1826, was master of one of the principal schools. He was educated at Leipzig, and afterwards studied astronomy at Berlin under Professor Encke. He resided in London about two years at Mr. Bruck's private observatory, and the discovery of the hyaline remains of which the outer wall of the globe is constituted. The deep green colour of the contents of these stellate embryos, and their subsequent changes into an orange colour, at once point out their close analogy with those of V. aureus. I have no doubt of their being merely modifications of the latter; and in fact they are so very frequently to be met with in intermixed, and on several occasions I have observed smooth and stellate globules in the interior of one and the same parent globe.

The organism described was first observed by Ehrenberg, under the name of Spharosira Volvox, also presents the appearance of a transparent globe set with green spots, but it differs from the foregoing in two important respects:

1. In the absence of any internal globules or embryos.
2. In the irregular size of the green granules lining the wall, which, instead of being of a uniform size, are of various dimensions.

Mr. Busk and Professor Williamson, in the first volume of the new series of Microscopical Society's Transactions, have furnished in great detail an account of the development of these curiously organised granules. From their observations, it appears that the green ciliated granules which stud the surface of the Volvox are produced from a single central embryonic mass by successive division by segmentation. Mr. Busk observed in these green granules a curious phenomenon.

It will also be observed, that each ciliated cell or zoospore, as it may analogously be termed, contains a green granular mass or masses, composed, for the most part probably, of chlorophyll granules and a more transparent body, which I suppose may be regarded as a nucleus, and derived, as it would appear, from one of the bright spheres which have been noticed before. At an early period after the maturity or completion of the zoospores they exhibit a minute circular clear space, or sometimes, but I think rarely, more than one, which is worthy of very attentive consideration. This space is of pretty uniform size in all cases, and about 1-0000ths of an inch in diameter. It may be situated in any part of the zoospore, or not infrequently in the base, or even in the midst of one or other of the bands of protoplasm connecting it with its neighbours. Its most important character is its transparency; it is an already known to be possessed by similar spaces or vacuoles in vegetable cells, but what appears to me a very curious, and as yet unnoticed, peculiarity of this contraction, consists in the fact that it is very regularly rhythmic. In several cases in which I have watched the process, this number of contractions occurs at some time, the contractions or pulsations occurred very regularly at intervals of about 38° to 41°. In one case, however, if was not misled in the observation, the interval was about twice this, namely, 1° 29'. The contraction, which appears to amount to complete obliteration of the cavity of the vacuole, takes place rapidly or suddenly, as it were, whilst the dilatation is

VOLTAITE. [Mineralogy, S. 1.]

VOLOX, a genus of organic beings referred by Ehrenberg to his family of Protista. Golubow was the first to doubt the correctness of Ehrenberg's classification, and the result has been that through the subsequent researches of Williamson, Busk, and Cobin, the species of Volvox are now regarded as forms of the vegetable kingdom.

The species consist in: V. globator, V. aureus, and V. stellatus. A fourth form is described by Ehrenberg under the name of Spharosira Volvox.

The following is Mr. Busk's account of these forms of Volvox:

"The more common and best known form of Volvox globator, to the naked eye, or under a low power, appears as a transparent sphere, the surface of which is studded with numerous regularly placed green granules or particles, and which, in the interior several green globules, of various sizes in different places, though nearly always of uniform size in one and the same parent globe.

"These internal globules, which are the young or embryo Zoosporæ, adhering to the wall of the parent globe, through the precise mode of connection is not very apparent. When thus affixed, they are in a different concentric plane to the smaller green granules. At a later period, and after they have attained a certain degree of development, these internal globules, or cell, exhibit precisely the same structure as the parent globe, or small granules, of them consisting in the deeper green colour of the internal globules. These however soon exhibit a more important distinctive character in the formation of a distinct cell-wall of considerable thickness around the dark-green globular mass. This wall becomes more extended and more distinct; and, after a time, the contents, from dark-green, change into a deep orange-yellow; and simultaneously with this change of colour the wall of the globe acquires increased thickness, and is stellate.

"The third form, or Volvox stellatus, differs in no respect from the second, except in the form of the internal globules, which exhibit a stellate aspect, caused by the projection on their surface of numerous conical eminences, formed of their globules and stellate embryo, the whole of which is then defined by the successive division of the hyaline substance. The deep green colour of the contents of these stellate embryos, and their subsequent changes into an orange colour, at once point out their close analogy with those of V. aureus. I have no doubt of their being merely modifications of the latter; and in fact they are so very frequently to be met with in intermixed, and on several occasions I have observed smooth and stellate globules in the interior of one and the same parent globe.

"The organism described was first observed by Ehrenberg, under the name of Spharosira Volvox, also presents the appearance of a transparent globe set with green spots, but it differs from the foregoing in two important respects:

1. In the absence of any internal globules or embryos.
2. In the irregular size of the green granules lining the wall, which, instead of being of a uniform size, are of various dimensions."
slow and gradual." This contraction of vacuolar sponges has since been observed by Cohn in a species of *Protozoa.*

Mr. Buxton sums up the result of his observations upon *Volvox cylindricus*:

1. That it originates in an apparently neculated discoid cell, which is generated in the interior of the parent, and liberated in a perfect stage though not fully matured form, within which are contained similar forms.

2. That the contents of this apparently neculated discoid cell, consisting of a granular material, and refractive amorphous (?) spherules, after a time undergo segmentation, at the same time exhibiting a distinct wall, beyond which is a delineated area of the disc itself, apparently a gelatinous constituent.

3. That this segmentation, attended with a corresponding augmentation in the number of the refractive spherules, terminates ultimately in the formation of numerous continuous particles or segments.

4. That these segments are gradually separated from each other, remaining connected only by elongated processes or filaments, and constituting the ciliated zoospores of the mature *Volvox.*

5. That these zoospores at first are simple masses of protoplasm, containing a transparent nuclear body, and that afterwards they present for a time clear circular spaces, which contract rhythmically at regular intervals; and are subsequently furnished with a brown eye-spot; and at a very early period have thick refractive plates, which arise from an elongated hyaline beak penetrating the parent cell-walls, and exert active movements external to it.

6. That in a concentric plane internal to these ciliated zoospores are placed the germs of future individuals destined to form the next generation.

**VOROSMARTY, MIHALY or MICHAEL, an eminent Hungarian poet and prose writer, was born at Nyére, in the county of Fejervar, called by the Germans Stihisweissenburg, in the year 1800. His father, whom he lost early, was a nobleman. Michael went in 1817 to Pesth to study law, and in 1824 he was admitted as an advocate, but he early adopted literature as a profession. In 1821 appeared his first drama, "King Solomon," founded on the History of King Solomon of Hungary; and in 1824 another drama, "King Sigismund," between which, in 1829, was published his romantic poem of "Triumph of Fidelity." It was as an epic poet that he attained the greatest celebrity: his "Zalan Fatíma," or Flight of Zalan, his "Érzékhajó," and his "Tündéryó," or Enchanted Valley, the first published in 1824 and the last in 1827, are considered the finest narrative poems in the Hungarian language.

For some years Vörösmarty was editor of the "Tudományos és Gyűjtemény," or Repository of Science, a monthly magazine, which lasted under his guidance, and that of others for a quarter of a century, and was during its continuance the chief organ of Hungarian periodical literature. He was afterwards concerned with Bajza and Schedel in the editorship of the "Athenaum," a periodical not unlike the London "Athenæum," which had for a time great and deserved success. In 1830, on the establishment of the Hungarian Academy at Pesth, he was appointed one of its members, and soon afterwards its secretary, and for some years his life flowed in an unbroken course of literary labors and literary fame. In general his reputation stood higher among the educated classes than among the people. The popularity of his lyric poems, the "Szócsat," or Appeal, written in 1840, enjoyed a double success; it rose at once to a strong popularity among the people, like that of the "Marcellina" in France, and to the Hungarian Academy represented the poet with a ducat for every line. Some of the lines of the "Szócsat," the subject of which is the fate and prospects of the Hungarian nation, have since acquired a melancholy increase of significance:

"If there are will, and some there must, To us a better line.
And if it come not, then come Death To our dark night.
And be our country, drowned in blood, Laid on a glorious bier."

It was natural that at the outbreak of the revolution in 1848 the poet of the "Szócsat" should be called on to take a part, and he was elected deputy for the county of Bacsa. His course in the Assembly however was far from meeting the approval of some of the more fiery patriots. The pope and imperialist Pókó, the Hungarian Burna, was so indignant at one of Vörösmarty's votes that in a poetical address to him he renounced his friendship. (Preface, p. 3.) On the last triumph of the Austrians Vörösmarty was brought to trial and condemned as a member of some of the revolutionary committees, but was released and pardoned after a short imprisonment. He however wrote a neat protest piece by him: the calamities of his country, the has been his lot deep melancholy, and lived for two or three years in retirement, without suffering pen and paper to come in his sight. At length, in 1854, his friends roused him in some degree from this state of depression, and he undertook a translation of Shakespeare, some of whose plays he had rendered into Hungarian in happier days. The task was still not completed when Vörösmarty died at Pesth, on the 9th of November, 1856.

An edition of the works of Vörösmarty was issued by his friends Bajza and Schedel as part of the collection of the Hungarian classics, entitled the "Nemzeti Könyvtár," or National Library. It was published in 1847. The divisions adopted for the writings are Lyric Poetry, Narrative Poems, Novels, Minor Poems, Prose, and Miscellaneous Writings in Prose, which are subdivided into Essays on Language and Literature, and Dramatic Criticism. The whole are comprised in one thick octavo volume, printed in double columns, but would occupy nine or ten octavo volumes. Vörösmarty's writings are more distinguished by classical correctness of form than for striking originality of substance. His narrative poems are written in hexameters on the classical model, for which the Hungarian is perhaps better adapted than any other modern language. His lyric as well as his epic poetry is estimated at a high value by native critics; but the very qualities that excite their admiration render their beauty difficult of transfer.
The Australian Alps commence at Wilson's Promontory, and extend into New South Wales by Mount Wellington. In this range rise the Murray and the numerous streams which, flowing southward, fall into the sea and form it into a river, having abundant water all the year round, whilst most of the large rivers which run into the interior become dry during the summer months. Further north, in the Warragong Chain, the Mumurundi beeches with their affluents take its source, and is likewise a perennial river. East and north of this are Yass Plains and the hilly tract inclosing Lake George. The elevated plains extend, under the name of Goulburn and Breadalbane Plains, about 40 miles farther north, to the southern extremity of Coolburn Range, which separates the Great Plains of the South from the Blue Mountains, east of which runs the Shoalhaven river to the sea. Blue Mountains commence in 34° 30' S. lat., and run northwest to the Monndilla Range, in 32° 40' S. lat. From this range the San, the Wollondilly, and the Macdonald rivers, all of which find their way to the sea through the Hawkesbury and Bullen Bay; on the west side descends the Lachlan and its affluents, which join the Mumurundi. The mountains are the highest in New South Wales, and extend to several hundred miles to the north and south of the city of Sydney, and connected with them are the Blue Mountains, which extends still farther to the west. The only part of this range is included between 150° and 151° E. long. which is a considerable portion of the ridge without trees, overgrown with bushes, and grassy; but on the rising grounds are forests composed mostly of apple trees, iron-bark, stringy-bark, and box.

The coast-line on the east extends in a general direction of north-north-east from Cape Howe to Cape Byron, where it recedes a little to the west. There are numerous harbours formed by the mouths of the rivers flowing into the Pacific. The chief of these, proceeding from south to north, are—Two-fold Bay, at the mouth of the Tawambo, immediately north of Cape Green, one of the boldest promontories along the coast; Barmouth, Bateman Bay, Sussex Haven, Gage's Bay, Shoolbroad Haven, Botany Bay, Sydney, Port Jackson, Broken Bay, Port Stephens, Farquhar and Harrington Inlets at the mouth of the Manning and Landows rivers, Port Macquarie, Trial Bay, Shoal Bay at the mouth of the Clarence River, in 30° 10' S. lat., which is separated from the M'urriedl by a headland, with its group of islands extending 70 miles from north to south. In this extent the shore presents every variety of appearance. From Cape Green to Shoalhaven River the cliffs are generally low; from Shoalhaven River, north of 30° S. lat., the distance increases, and the range of bold perpendicular cliffs of sandstone lying in horizontal strata, occasionally interrupted by sandy beaches, the high land retiring to a considerable distance. Numerous sand-hills occur along the remaining part of the coast. Port Stephens is a bar-harbour, so that small vessels only can enter it; those of larger description are compelled to anchor offshore.
outside. In some parts especially north of Trial Bay (30° 50' S. lat.) and south of the month of Clarence River, are tracts of coast many miles in length, where it is rocky and difficult to reach. The harbours are only found at the mouths of the numerous rivers.

**Rivers.—**The larger rivers which drain the country between the Pacific and the watershed have water all the year round. They generally flow in beds which are deeply incised, being several hundred feet deep in the common levels of the country, which rise perpendicularly, or nearly so, from 100 to 200 feet and frequently higher, so that the streams are inaccessible, except at a few places. They are of little use for navigation, irrigation or for transport. The **Shoal Water River,** the most northern and considerable of the rivers of this region, rises on the table-lands east of the Warragong Mountains, and runs about 90 miles northward, measured in a straight line, and then about 40 miles eastward. About 200 miles and its mouth occurs the last rapid, np to which the tide flows. The mouth of the river is much obstructed by shoals and sand-banks. The **Hastings** falls into Broken Bay. It rises under the name of Wollondilly, on the connecting table-lands, and receives nearly all the waters which are collected on them. It flows into a deep bed, sinking into a deep ravine, when it is no longer accessible. The last rapids occur near Windsor, from which place it is navigable for moderate vessels. When it leaves Windsor, the current is not strong, and it has about 100 miles at least following the windings of the river, whose waters are fresh for 30 miles below the town. Its estuary, Broken Bay, is surrounded by rocks, and has several good anchorages even for large vessels, the best of which is called Pittwater. Beyond Pittwater is the course of the river, which is 24 miles, and are measured by the surveyors.

Sometimes the floods of this river rise to 90 feet above its usual level, and the inundations then lay waste the fertile tracts on its banks. **Georges River** falls into Botany Bay. It runs hardly 60 miles, but is navigable for boats from Liverpool, down-wards, a distance of about 12 miles in a direct line, but 24 miles following the windings of its course. **Hunter River** disembogues into Port Hunter. It has two great branches, one called Hunter and the other (Gosford River,) which enters the coast at the bar on the north side of the entrance of the river. The river is navigable for about three miles. The navigation begins at Maitland, about 20 miles from Port Hunter by land, but nearly 40 miles by water, and a steam-boat plies regularly between that town and Sydney. This river often rises rapidly after heavy rains, and in some places to the height of 40 feet.

The navigable rivers which drain the countries north of the Hunter are the Manning, Hastings, Apley, Clarence, and Wallagaraugh. The Manning, and Clarence, fall into Port Macquarie, which is a bar-harbour, admitting only vessels of 100 tons burden, and it is dangerous to enter, except at full tide, on account of the rapid current, which sends vessels ashore upon the shoals on the northern side of its entrance. The bar in the entrance of the river is the largest class, except when the wind blows strong on the shore. Within the bar is secure anchorage for a great number of vessels.

**North of Port Macquarie** is the valley which is drained by the Apley or Mac Leay River, which divides about 12 miles from the sea into two branches, inclosing a large island. The main branch at the northern end forms the harbour of Trial Bay, which has a bar across, having from 15 to 17 fathoms deep in it. This branch of the river has a distance of more than 50 miles from the sea, where farther progress is impeded by a fall, which occurs where the river issues from a narrow glen, whose sides rise 900 feet above its bed. Below this point the river runs through a wide valley, in which there are some plains destitute of timber, and gently-rising hills covered with opening forests and grassy pastures. Farther north is the valley of the Clarence River. **The mouth of the river is at Shool Bay, 29° 20' S. lat.** The river is about 120 miles in length, and considerable in width at high tides. **Brisbane River** falls into Moreton Bay, and is navigable by ships drawing 16 feet of water 20 miles np, at which point a ridge of rocks crosses the bed, but to a distance of two or three miles north the river it may be navigated by some vessels. Several of its tributaries are also navigable for some miles from their mouths. The country on both banks of the river presents an alternation of hills and level tracts. The soil, which is very good, is overgrown with high trees, and coppices of great magnitude. The highest hills lie on the north side of the river, where some rise from 700 to 800 feet. The **farthest sources** of the Brisbane are in the Coast Range, which here offers an easy passage to the interior by a gap which occurs south of the North of Mount Mitchell, which is 4120 feet above the sea.

All the rivers draining the interior of New South Wales, as far as it is known, appear to belong to the river basin of the Murray. The rivers composing this extensive system rise in the Eucalyptus districts of the high lands running north and south through New South Wales. The Murray itself we have noticed as dividing the colony from Victoria, and it enters South Australia at Table-land, 143° E. long., and then running east, flowing for about 90 miles in a direct line, it turns to the south and enters the sea at Encounter Bay. The Murraybridge, after it has itself received the Lachlan, falls into the Murray in 143° E. long. The Darling, by its upper branches, drains the country extending from 22° to 25° S. lat. Its most northern part, the Condamine, rises on the Darling Downs, in 29° S. lat., runs northward as far as 26° S. lat., 151° 4' E. long., then turns westward to 149° E. long., and then south-westward till it joins the Darling on its left bank. From the south-east it receives the Bogan, a considerable stream, rising in the Harvey Range; and it is probable that the Macquarie, at least during the rainy season, disembogues into it part of its water from the marsh in which it is lost.

Geological and account of the geology of the island has been given under **Australia,** S. 2. Sir R. I. Murchison had asserted that gold must exist in the country under certain formations; and the same theory had been promulgated in the colony by the Rev. W. B. Clarke, who, on the 19th February, 1860, stated that for 60 miles of the river running north and south through Victoria and New South Wales, were of the same formation as those of the Sierra Nevada in California, and the Ural Mountains in Russia, namely, granite, with gneisses and schistose slate; but it was not till 1849 that the actual existence of gold was discovered. In 1861 further discoveries were made, Mr. Hargraves disclosed the places where he had found gold, and when the government officer was sent to examine the places, he was found to be in the correct. Numerous licences for constructions were given by the governor to grant licences to diggers at 30s. per month. The first discoverers obtained the gold by washing the detritus from the beds of the creeks, and the earth from the shores; but it was soon found that the richest deposits were in the quartz, and means were found to crush the rock and obtain the gold. On August 5th the governor issued a notice that the licences would only apply to the gold-washers, and that on gold obtained by this method only a royalty of 5 per cent, would be charged. A royal commission was appointed to inquire into the matter. policemen were appointed to the various stations, and escorts furnished for bringing the gold from the diggings to the ports of Sydney or Melbourne. In a short time the towns and villages were deserted, all the usual avocations abandoned, and the roads of the colony became deserted. Twenty men on public labour repaired to the diggings. An immigration ensued almost without a parallel.

Respecting other metals we have little to add with what is said under **Australia,** S. 2.

**Iron-ore is known to exist in several places, especially on the west of Blue Mountains. Several extensive coal-measures have been found, two of which are worked. Those found near the mouth of the Hunter River, near Newcastle, are extensively wrought, and their produce is shipped to Sydney. The coal-beds near Western Port are also very large, and have been worked for several years. Limestone is abundant in some places, and some kinds of marble are worked on the banks of the Wollondilly.**

**Soil, Agriculture, and Agricultural Productions.**—The soil of so extensive a country must necessarily vary greatly. Many parts are distinguished for their fertility, and it is probable that at least one-fourth part is well adapted for culti- vation. The most extensive portions of the country are very suitable for sheep and cattle. In addition to the various species of grain and artificial European fruits and vegetables, that succeed well in various places, the sugar-cane, the vine, and tobacco are raised. Although the growth of grain has been constantly increasing and the production of grain has increased in the exporting country, and the influx of population in consequence of the discovery of the gold-fields must render it for a consider- able time still more so. The colonists have been at some pains to introduce many kinds of fruit-trees and vegetables, and they have in most cases done it with tolerable
success. There are oranges, lemons, citrons, nectarines, apricots, peaches, plums, cherries, figs, quinces, pears, apples, mulberries, pomegranates, grapes, raspberries, strawberries, bananas, gooseberries, pineapples, gooseberries, currants; almonds, walnuts, chestnuts, and hickory nuts, which have been introduced from England, and the wool was of indifferent quality; but as soon as it became evident that wool might become a source of wealth, and yield an important article of export to the mother country, several landed proprietors were at considerable expense introduced. They are fine large animals. In some parts, especially on the Plains of Bathurst, the dairies are well attended to, butter being made to a great extent, and also cheese not inferior to the common cheeses of England. Bullocks are mostly used for draught. The horses are remarkably hardy and can undergo great fatigues. Pigs find abundant food in the uncultivated tracts, and are easily fattened with maize. Goats have been introduced, and thrive amazingly in those parts which have a hilly country.

Poultry is in great abundance: geese, ducks, turkeys, guinea-fowls, and common fowls thrive surprisingly, without any particular care being taken of them.

Industry and Manufactures.—The manufacturing industry of this colony has made considerable progress, though the production and export of native commodities form the staple of the occupation of the inhabitants. The most numerous manufacturing establishments are the mills for grinding and dressing corn, turned without water, horses, or steam. There are also manufactories of woollen-cloth, hats, soap and candles, and of articles of furniture; distilleries, breweries, iron- and brass-foundries, rope-yards, and ship-building yards. As spermaceti-whales and black whales frequent the sea adjacent to the eastern entrance of Bass's Strait and the strait itself, and a great number of seals are found on the islands in the same part of the sea, the whale and seal fishery became a source of gain to the colonists, and is still carried on, though it has fallen off considerably.

Commerce.—New South Wales, considered as a commercial country, holds a very high rank among our colonies, if its population is taken into account. Including the large quantities of wool, tallow, hides, and sheep-skins, Great Britain sends an average of 3,000,000 to the value of 4,060,196; and exported articles to the value of 6,981,002. These amounts have decreased in the years 1856 and 1857, but are still very large. Considerable quantities of gold also pass through Sydney.

The other counties do not occupy the whole of the districts, nor do the districts occupy the whole of the territory, but it is a regulation of government that no land can be sold beyond their limits. The extreme boundaries of county lands have come therefore to be called the boundaries of our colonies. Since the discovery of these lands, a different system is followed in the management and civil government of them.

Within the boundaries the whole country is divided into police districts, each having a bench of petty sessions in a magistrate; and these districts which are of unequal size, there are at present about 40. Beyond the boundaries the country is also roughly divided into districts, in each of which there is a commissioner of crown lands, who is the chief officer. In 1817, Captain John Lawson, Mr. Windsor, Mr. Mitchell, and Dr. Leichhardt, who, leaving New South Wales, reached the Gulf of Carpentaria, and who, on a second journey, lost his life in the interior. The results of their discoveries have been given in the geographical notices of Australia and of the several colonies.
Blue Mountains, situated on the upper part of the Macquarie. It derived its importance at first from being the chief place of trade of the rich pastoral, Bathurst, Plains, which surround it. It has since become of still greater importance from its vicinity to the gold diggings of Ophir, which lie from 20 to 30 miles west from it. Boyd, or East Boyd, as it is sometimes called, is a small but fine portion of the southern border of the colony, on the mouth of the river Towamba, which here falls into Twofold Bay. Brisbane is at the northern extremity of the colony, situated on the river Logan, the principal river of the province. It is a flourishing town, in an agricultural district. Tobacco and wine are produced. Campbelltown is on the coast, about 20 miles S. from Sydney, and has considerable trade and manufactures, particularly of leather. Liverpool is about 16 miles W. from Sydney, and is a coasting town, being an inland town, surrounded by a rich and well cultivated country, which secures it much retail business. Macquarie, or Port Macquarie, is a small but increasing town, at the mouth of the river Hastings, which a little higher up receives the Wilson and Maria rivers, and forms a tolerably safe bay. It is about 120 miles N. from Hunter River. Maitland is on the right bank and about 40 miles from the junction of Hunter River, at the junction of the Walls creek. The river is navigable for many miles.

The following table will give an idea of the different parts of the colony:

Moldavia is divided into Upper Moldavia, or Terna-de-Sues, which is subdivided into 6 districts, and Lower Moldavia, or Terna-de-Shoss, which is subdivided into 7 districts. Each district is governed by an officer called Ispravniks.
WALLICH, NATHANIEL, M.D. and Ph.D., F.R.S.

London and Edinburgh, a celebrated botanist, was born at Copenhagen on Jan. 28th, 1786. He commenced his botanical studies under the direction of Professor Vahl, and went to India in 1801, and in one-and-twenty years of constant employment in that country he achieved an admittance to the academic and practical bibliography of the University of Copenhagen.

In 1815 he was nominated to the temporary charge of the Botanic Garden at Calcutta, which appointment was subsequently renewed, and in 1823 he was appointed Superintendent of the Garden. He was the first to introduce a printing-machine in Botany, and his publications were embellished with fine engravings of plants and flowers. The Journal of the Asiatic Society of Bengal is largely indebted to Dr. Wallich's exertions for its completeness. He has collected more than 12,000 plants, and many of the varieties he has introduced have contributed towards the flora of India.

Dr. Wallich's exertions during the thirteen years that elapsed before his first return to Europe added greatly to the extent and value of the previously extensive collections of this naturalist, without a rivalling the magnificent quantity of hitherto unknown and beautiful plants. In 1830 Dr. Wallich made a botanical excursion to Nepal, in the course of which he collected a great variety of plants, many of which he forwarded to London. A severe fever, caught in his descent to the plains, confined him to his bed for two months and compelled him to seek benefit from a voyage to Penang, Singapore, and some other places in the Straits of Malacca, from which, after an absence of five months, he returned to Calcutta in 1832. Rich in collections and with renewed health. In 1824 he published the catalogue of a selection from his Nepal collection, under the title of 'Tentamen Flora Nepalensia Illustratum,' of which two numbers, containing 20 plates, were published in 1830. He was then invited to attend the kettle, and the increase of the Botanic Gardens of England, and to become chairman of the Botanical Society of London. At this time he completed his work, entitled 'Plantae Asiaticae Rariores,' consisting of 300 beautifully executed coloured plates. In 1833 Dr. Wallich returned to India and resumed the charge of the Botanical Garden, which he had left 14 years before. In 1837, the first number of the journal of the Botanical Society of London was published, and in 1839 the whole of the society's transactions were published. Dr. Wallich was a member of the British and Foreign Antiquarian Society, and a fellow of the Linnean Society. He was a man of warm affections, ready wit, and pleasing manners, and devoted to his attachment to his favourite science. He must not be forgotten that he did more than any one else to introduce the gardens and greenhouses of England the beautiful and luxuriant plants of India, and it is from his collections and descriptions, and presentations to our public and private gardens, that we are indebted more than to any other source for our acquaintance with most of the plants that are found in England.

He died at his house in Upper Gower-street, London, on the 28th of April 1854, in the 69th year of his age.

WALTER, JOHN, late manager and principal proprietor of The Times' newspaper, was born in 1764. His father, John Walter, who was born in 1739, was known as the merchandising printer, from his having obtained a patent for an invention named Logography, or the art of printing with entire words, their roots, and terminations, instead of the letters of the alphabet. He was also a manager of the Koenig printing-office in the Strand, and it is on record that he published the first number of The Times,' and was during fifteen years printer to the Board of Customs, but that employment was taken from him about 1806, in consequence of the West Indian Act. Sir Richard Grenville, a former Lord Melville's administration at the Admiralty, he died November 16, 1812, at Tweddington, Middlesex.

The late John Walter became a joint proprietor and the exclusive manager of 'The Times' at the commencement of the year 1803. It would not be easy to describe the improvements which were made in 'The Times' under his management. The magnificent sums paid to the editor and to those literary gentlemen of the highest class who furnished the leading articles, the large staff of reporters at liberal salaries for parliamentary debates, law proceedings, and public meetings, the large amount and accuracy of information, the almost universal correspondence, the competition with the government for priority of intelligence, the distinct arrangement of the whole matter, the firmness of power for the printing, and the marvellous rapidity with which the whole is produced, have raised 'The Times' to a position of social and political importance in which it is unparalleled in Great Britain and in Europe.

The invention of the printing-machine, and the steam-engine as a moving power have produced so great a revolution in the process of printing, as to require a brief statement of the origin and progress of the invention. As early as 1804 an ingenious combinator named Thomas Martin had made the model of a machine for printing, which met with the approval of Mr. Walter, who expended a considerable sum in the attempt to complete the machine; but his health endangered his funds, and his father, who had hitherto assisted him in the business, was unable to support the attempt was abandoned. About the same period Mr. Kenig, a native of Germany, had made some progress in the contrivance of a machine for printing. Having met with no encouragement from the scientific world, he, who was invited to Mr. Bensley's well-known printing-office, was being satisfied as to the feasibility of the projected improvement, supplied the necessary funds. An ingenious assistant of the name of Baner was also engaged, and the work proceeded till the invention was completed. Baner, who was losing the sale of his additional funds, invited the late Mr. George Woodfall, and Mr. Richard Taylor, both well-known printers, to join him and Mr. Kenig in taking out a patent, which they did, the machine even then being so far advanced as to satisfy them as to the prospect of success. The improvements in the specifications were patented March 29, 1810. It was taken out in the name of Frederic Kenig, and was assigned by articles of partnership to the firm of Baner, Kenig, Woodfall, and Taylor. Mr. Kenig states (The Times, December 8, 1814) that "about the first of the New Annual Register" for 1810, "Principal Occurrences," was printed by machine, and it is, I have doubt, the first part of a book ever printed by a machine. The machine was set to work regularly in April, 1811. Another patent for a machine on an improved plan was taken out October 30, 1812. It was completed in December that year, and printed about 600 copies an hour. A third patent for another improved machine was taken out July 25, 1813. Mr. Kenig's patent for a printing machine in 1814 was in fact being independent of the motive power. Mr. Perry, of the Morning Chronicle was applied to, but declined to purchase a machine. Mr. Walter, however, according to the instructions of Mr. Kenig, took one of the specifications, and gave an order for two machines, which were to be worked by the power of a steam engine. Notwithstanding violent opposition from the pressmen, the machines were completed on adjoining premises, and on the 29th of November, 1814, 'The Times' was printed for the first time by machines worked by steam-power. The number impressed in the hour was then about 1100. Great improvements have since been made by the late Professor Edward Wodder and others, in the machines for printing books as well as newspapers. About 12,000 copies per hour are turned out by 'The Times,' and the total number per day is upwards of 50,000.

Mr. Walter married in 1818. Having purchased a fine estate in Berkshire, he became a candidate for the re-presentation of that county in Parliament, and was returned. He was re-elected in 1835, but in 1837 resigned his seat in consequence of the opinions of the majority of those who had elected him being opposed to his own on the question of the new Poor Laws. In 1840 he offered himself for the borough of Nottingham, but was defeated. He returned for the borough of Nottingham, and at the general election the same year announced himself as a candidate, but in consequence of serious rioting, withdrew half an hour before the poll. He died July 28, 1847, at his residence, Printing-House Square, London.

WARBURTON, ELIOT BARTholOMewGEORGE, eldest son of the late Major G. Warburton, of Aughrim, county Galway, Inspector-General of Constabulary in
Ireland, was born in 1800: he represented a branch of an old Cheshire family. He received his education at home, and under the care of a tutor; then entered Queen's Col-
lege, Cambridge, but after his second term he migrated to Trinity, where he took his degree. He was subsequently
called to the bar, but soon ceased to practise, and turned his affairs to the profit of the law, and the imme-
readly valuable theme to his life, he first became known to the world as an author by his captivating work on the East and Eastern Travel, entitled the 'Crescent and the Cross,' which was first published in 1846. This work was at once admired in the West, and in the East, and its second edition (1848) in the 13th edition. It was followed in 1849 by his 'Prince Rupert and the Cavaliers,' a brilliant history and vindication of the gallant prince, to which the chivalrously distinguished himself in the civil war under Charles I. He was known as Mr. W. Hartopp; his father was a distinguished public servant, and a second son. After the reformatory and illustrative period of the 18th century. Shortly afterwards he wrote the Memoirs of Horace Walpole and his Contem-
poraries.' His last work, which was published after his death, is entitled 'Darien, or the Merchant Prince;' it is a tale founded on the colony established about the middle of the 18th century by a Scottish adventurer named Paterson, on that portion of the northern coast of South America which abuts on the Isthmus of Panama, and is known by the appel-
lation of Darien. The novel was followed by another, the Life of the late E. Grove, Esq., of Shenton Park, Staffordshire, and niece of Sir E. Credock Hartopp, Bart., by whom he left two sons. He was lost in the ill-fated ship Amazon, which was burnt off the Land's End, January 4, 1822. He had married Miss Mary Turner, daughter of Mr. John Ward, a Spanish merchant resident at Gibraltar, who had married a Miss Raphael, a Spanish Jewess; and was born on the 19th of March, 1765. He was educated at a small school, and a grammar school, and was a pupil of Dr. Cyril Jackson. He was called to the bar at the Inner Temple in 1790. Having gone the Northern Circuit without much success, he secured employment in cases before the Privy Council. In 1805 he was appointed by Mr. Pitt, then one of the English judges, a special under-secretary for the Foreign Department, and was retired from the legal profession in order to undertake the more congenial duties of under-secretary of State for Foreign Affairs. From 1807 till 1811 he was a Lord of the Admi-
ralty under the late Lord Melville and the Right Hon. Charles Yorke; he served the office of Clerk of the Ordnance from the latter date till 1823, when he was appointed one of the auditors of the Civil List— a post which has since been abolished. He served as high sheriff for the county of Hertford in 1832, and for many years held a seat in parliament, which he entered in 1802 as member for the borough of Cockermouth, and subsequently for the disfranchised constituency of Hazlemere. Amongst all his political and literary labours, Mr. Ward found time and leisure for the composition of several works of political and historical interest. Of the former, the best known is his 'History of the Law of Nations in Europe from the time of the Greeks and Romans to the age of Grotius,' which was published in 1795, and was principally written during his breadth of mind, and sense of principle. Of his novels, 'Tremains' and 'De Vere' are those which have attained the widest circulation. The former was published anonymously in 1826, and the latter in 1827. His other works are— an Inquiry into the Con-
duct of European Wars,' 1803, a pamphlet which first en-
listed on his side the patronage and favour of Pitt; 'Illustra-
tions of Human Life,' 1837; 'Pictures of the World,' 1838; 'Historical Essay on the Revolution of 1648;' 1858; and, lastly, 'De Clifford,' a novel, published in 1841.

From the middle of 1809 till late in life Mr. Ward kept a political diary, which has since been published down to the year 1851. It is valuable as an historical document, and as throwing some light on the state of things under the Per-
cival and Liverpool administrations. Mixing largely with the world of politicians, and being equally skilful in gather-
ing and prompt in recording the gossip of the day, Mr. Ward was enabled to give to his records just the facts which really cur-
rented in London. 'The Diary' is at present withheld from publica-
tion, owing to the warlike nature of its purpose, and the severity of its comments on living statesmen. The 'Diary' will be found in the 'Memoirs of the Political and Literary Life of Robert Plumner Ward, Esq.,' published in 1850 by his friend and relative the Hon. Edmund Phillpotts, 2 vols. 8vo. Mr. Ward was twice married: first, in 1798, to a daughter of C. J. Maling, Esq., by the Dowager Countess of Mulgrave; secondly, in 1828, to Jane, daughter of the Hon. and Rev. George Hamilton, son of the seventh Earl of Ahermon (by whom he had a son, Robert, and two daughters, Misses Hamilton). He had the fortune to see nearly all his children carried off by consumption, with the exception of his only son by his first wife, now Sir Henry George Ward, governor of Ceylon. He died at Ockever Hall, on the 13th of August, 1846.

RALPH, D.D., was born at Dalkeith, in the county of Mid-Lothian, Scotland, on the 22nd of De-
cember, 1779. His father, William Wardlaw, was in business as a merchant, his mother, Anne Fisher, was daughter of James Fisher, and great-granddaughter of Ebenezer Erskine, two of the founders of the Scotch Secession Church. Ralph received his early education at the public schools of Glasgow, to which city his parents removed shortly after his birth. He entered the University of Glasgow in October, 1797, and was graduated in the university of Edinburgh as a doctor of divinity in 1798. He was elected an M.R.C.S., and a member of the Royal College of Surgeons of Edinburgh, in 1798. He was elected to the presidency of the University of Edinburgh in 1799, and was returned for the sheriffdom of Mid-Lothian, in 1799. The discipline of the University of Edinburgh was at this time under the charge of Dr. John Burns, who was then a young man, and was elected to this chair by the students in 1798. He entered the University of Glasgow in October, 1797, and was graduated in the university of Edinburgh as a doctor of divinity in 1798. He was elected an M.R.C.S., and a member of the Royal College of Surgeons of Edinburgh, in 1798. He was elected to the presidency of the University of Edinburgh in 1799, and was returned for the sheriffdom of Mid-Lothian, in 1799. The discipline of the University of Edinburgh was at this time under the charge of Dr. John Burns, who was then a young man, and was elected to this chair by the students in 1798.
times, he bestowed 18,000£, and he contributed largely for church purposes, particularly in his own county of Gloucester, and in Nova Scotia. He founded an hospital at Leamington, which bears his name; and one for lunatics on Headington Hill, near Oxford. To King's College in London he presented anonymously several donations of 500£ each; but to Queen's College, Harrow, the proceeds of his contributions was upwards of 25,000£. This institution was commenced by Mr. Sands Cox as a school of medicine, and Dr. Warneford literally afforded pecuniary assistance, through inducing him to extend the school to a college, which was ultimately patronised by royalty. When it was found desirable to add other departments of education, Dr. Warneford was again the chief contributor; and desirous that religious instruction should be afforded, he founded the college with the desire of promoting the reading of the sacred books and the study of the humanities and the liberal arts. In 1844, in recognition of his wide-spread beneficence, the bishop of Gloucester conferred upon him an honorary canonry in Gloucester Cathedral; and in 1846 in a state of health he was erected to the Warneford Lunatic Asylum at Oxford, the expense being defrayed by public subscription. He died at Bournon on January 11, 1855, enjoying good health till within a few days of his death. He bequeathed 2000£, to the Christian Knowledge Society, to be employed for the Propagation of the Gospel, in addition to previous gifts.

WART-CRESS. [Sennabria, S. J.]

WARWICKITE. [Mineralogy, S. 1.]

WASHINGTON, a Territory of the United States of North America, bounded by 49° N. lat., 110° 30' and 124° W. long. It is bounded E. by the Rocky Mountains, which separate it from the Territory of Nebraska; N. by the parallel of 49° N. lat., which separates it from the Territory of Oregon; and W. by the parallel of 45° N. lat., which is the boundary of the Territory of Oregon. The area is 123,022 square miles. The population in 1857 was estimated at 10,000. At the Census of 1850 Washington formed a part of the Territory of Oregon, which contained 13,294 inhabitants. The county separated in order to form a separate state in 1853, and was organized as a Territory of Washington, then contained less than 2000 inhabitants, exclusive of the native Indians, who probably number about 7000 or 8000.

In its general character Washington has a marked resemblance to Oregon. The surface is greatly broken, it being traversed from south to north by three parallel ranges of mountains, the northern prolongation of the Oregon ranges, while the Rocky Mountains, as in that Territory, form its southern boundary. The chief disagreeable feature is the residue of Columbia to the entrance of Gray's Harbour, or, as it was named by Vancouver, Whidbey's Bay, a distance of 46 miles, is rocky and almost unbroken. The entrance to Gray's Harbour is about 24 miles across, but the harbour itself extends to a width of 12 miles, and is 12 miles deep. It affords well-sheltered anchorage in some places, but it is everywhere encroached on by sand-banks, and its mouth is obstructed by a bar, which only admits the passage of vessels drawing under 10 feet of water. From Gray's Harbour to Cape Flattery, or Cape Disappointment, a lofty promontory at the southern end of Juan de Fuca Strait, a distance of about 80 miles, the coast is high, rocky, and only broken by two or three unimportant streams. The Strait of Juan de Fuca, which forms the northern boundary of the coast of Washington, is a vast arm of the sea, about 10 miles wide at its mouth and 100 miles deep. [Vancouver Island, S. 2.] The southern coast consists of perpendicular sandy cliffs of moderate elevation, from which the land gradually rises towards the sea. The entrance of the strait is about 5 miles from the mouth of the strait is a long low sandy point which forms a good anchoring-ground; and beyond this is a deep bay about 9 miles across, and 3 miles from its eastern point is Protection Island is named by Vancouver from its position at the entrance to Port Discovery. Immediately beyond Port Discovery is Port Hudson, an equally safe and good though somewhat smaller harbour: Vancouver and Wilkes unite in describing these as among the very finest harbours on the whole coast of the north-west. From this harbour is a deep inlet named Admiralty Inlet, which soon divides into two arms—the smaller one named Hood's Canal, bearing to the south-west, and stretching far into the interior; while the main arm proceeds due south for about 80 miles, where it terminates in two smaller named Puget's Sound.

Both these branches afford good anchorage; but Puget's Sound is broken by several inlets, and affords the
The greatest possible security and ample space. Vancouver speaks of these harbours and the contiguous country in such terms as might suggest the suspicion that he had been carried away by the ardent feelings of a discoverer; but Mr. Wilkes, the commander of the U.S. Exploring Expedition, fully corroborates all that Vancouver has said. He says, the

"there is nothing can exceed the beauty of these waters and their safety: not a shoal exists within the straits of Juan de Fuca, Admiralty Inlet, Puget's Sound, or Hood's Canal, that can in any wise interrupt their navigation by a 74-gun ship. I very often think there is nothing in the world that possesses waters equal to these." It is around Puget's Sound that the commerce of the Territory is chiefly establishing itself. Numerous settlements have been already formed along its shores. The tide rises 18 feet in Puget's Sound. The Sound is full of islands, and receives several small rivers.

Like Oregon, this Territory is naturally divided into three nearly parallel districts, determined by the course of the mountain ranges: a western, or coast section; the middle section, lying between the Cascade and the Blue Mountains; and the Rocky Mountains section. The western section lies between the Cascade Mountains and the sea, and is much broken in surface, being intersected by spurs from the Plateau, and the greatest part of it is covered with forests of lofty pines; firs often occur from 200 to 300 feet in height, and of corresponding girth, and some of the pines rise to a height of 200 feet without a branch. The most prevalent trees besides pines are firs, oaks, and aspen, and on the higher points, growth of hazels, roses, &c. The hills are generally of basalt, and some, like Mount Olympus, near Joan de Fuca Strait, are of considerable altitude. The soil is in parts a light brown loam, in others a light vegetable mould with a sand, or shell, or mud bottom. Generally, the soil is of good fertility. The river-bottoms afford good farming-land, the prairies and the uplands excellent pasture-ground. The climate is mild and salubrious, though somewhat moist; the winters are temperate, and snow seldom lies long on the ground. Game abounds.

The Cascade Mountains continue, as in Oregon, in a generally northern direction, and about 150 miles from the coast. Their highest cones rise to an altitude of upwards of 13,000 feet, and they form a barrier of very difficult passage between the western and middle sections of the territory. The country between the Cascade and Blue Ranges is wider than the corresponding district in Oregon. Between the Snake and the Flathead or Clarkes rivers, and between the ranges of the Salmon and Cowlitz, nearly 200 miles in length and 100 miles across in its widest part. The soil is araceous, and the country little fitted for tillage; but the plain is covered with a good grass, and is well suited for immense flocks and herds. The river-bottoms have little soil, but generally productive. The hills are comparatively bare of wood, and infertile. The climate of this middle section is cooler, drier, and more salubrious than in the western section; but the variability of the climate is much greater. No dew falls here. The Blue Mountains are considerably broken and interrupted, but generally run north and south. The country east of them to the Rocky Mountains is interrupted throughout by offsets from the Rocky range, and transverse ranges connecting the main chain. Nothing can well exceed the wild magnificence of much of this country, with its vast and snow-clad mountainous tracts, deep valleys, tremendous gorges, lofty catastra, and rushing torrents. It is of course little suited for agricultural operations, but the bases of the hills and the valleys are excellent for grazing. The soil, which from which flow the head streams of the Columbia, the Spokane, and the Flathead rivers, are spots of remarkable fertility as well as of surpassing beauty. But all this district, as also the Indians, who are a warlike and implacable race. The chief distinction of the Indian tribes is on hunting, and they barter the furs to the servants of the Hudson's Bay Company for tobacco and articles of European manufacture; but the fur-bearing animals are rapidly diminishing. There are three or two practicable passes in this range along the territory of Washington, but they are much more difficult than the Great North Pass.

The principal river in the Columbia, which belongs equally to Washington and Oregon; it is described under Columbia River. Its northern branches rise in the Rocky Mountains within the Hudson's Bay Territories, and unite in Washington; the united stream traversing the Territory in a generally southern direction, and receiving numerous tributaries. It forms the Columbia by the junction of the Saphin or Lewis rivers. The principal tributaries of the northern branch of the Columbia are the Kootanai or Flat Bow, the Flathead or Clarke, and the Spokane rivers: they are all very rapid streams, but navigable by boats for some distance. The chief river north of the Columbia is the Chehalis, which rises in the mountains west of the Coast Range, and pursues its very tortuous course to its outfall in Gray's Harbour. Its course is very rapid, and it is only navigable by canoes; it receives several small streams from the high grounds about Hood's Canal and Puget's Sound. The Nichols and Tenaliqui, or Tenaliqui river, is a very rapid stream, but not navigable for some distance, but will probably prove of greater value for their mechanical power. In the interior are numerous lakes, the larger being chiefly expansions of the northern branches of the Columbia, the Spokane, and the Clarkes.

At present the breeding of horses and cattle has attracted most attention from the settlers, but agriculture is rapidly extending. The productions are similar to those of Oregon. Wheat is the chief grain crop; maize has not been much cultivated. The soil is of a generally clayey nature, and affords an unlimited quantity of fine timber. Coal is found in the neighbourhood of Puget's Sound, and near the Chehalis and Monticello rivers. Iron and other metals have been found; but mining operations have as yet been little heeded. A few United States settlers have been engaged in the dense forests of the Territory, and probably will become an important part of the industry of Washington. All the rivers abound in fish; salmon being especially abundant. Fish also abound on the coasts. Whales frequent the coasts and the mouth of Juan de Fuca Strait. Nothing has hitherto been discovered by the climate of Washington that would be likely to prevent the effluvia of Olympia, on the right bank of the Tenaliqui or Shute's River, at its entrance into Puget's Sound. This town boasts of its hotel, store, saw- and grist-mills—the first in the Territory—newspaper, &c.; and contains 300 inhabitants. The town of Hood's Mouth, on the right bank of the Columbia is, below Fort Vancouver; Monticello, the capital of Lewis county, and the place where the convention was held which led to the separation of Washington from Oregon; Ninimock, on the east bank of the Columbia, 6 miles below the city of Columbia, has 14 inhabitants; and Pacific City, on the right bank of the Columbia at its entrance into the Pacific Ocean, which contains 120 inhabitants. The Territorial Assembly consists of 12 members, for three years, but one-third to vacate their seats each year; and a House of Representatives of 18 members, elected annually. The governor is appointed by the president and senate for four years. All laws passed by the legislature must be submitted for confirmation to Congress. No law can be passed interfering with the primary disposal of the soil; or taxing the property of non-residents higher than that of residents. Sections 16 and 36 in every township are devoted to public and school purposes.

(Vancouver; Wilkes; Lewis and Clarke; Fremont, &c.; Gazetters of United States; United States Census; American Almanac, &c.)

WATT, JAMES, the eldest son of the celebrated James Watt, was born on 5th of February, 1769, and died, unmarried, at his seat, Aston Hall, in Warwickshire, near Birmingham, on 7th June 1788. Mr. Watt had early directed his son's attention to natural
philosophy and as a practical study of mineralogy. It is scarcely known, and has not been recorded in any previous biographical work, that he was a man of science and a practical engineer. He was one of the secretaries of the Literary and Philosophical Society of Manchester, then just founded, one of the earliest, and perhaps still the most distinguished of the provincial scientific associations. To the 'Memoirs' of this society be Mr. James Watt, who, on the 21st of June 1823, in a humorous sketch, gave an account of the discovery of the carbonate of barytes at Angl-zark, he was the first to describe, in the paper here indebted, to the circumstances which attended its occurrence, and to make known the fact that the specimen examined and the analyses of the mineral from which it was prepared the aurate, which had been recently introduced into medical use by Mr. Adair Crawford, F.R.S., had been obtained from that locality. He also were some of the earliest experiments on the poisonous effects of the combinations of barytes.

A remarkable episode now occurred in the life of the young philosopher—for such, at this period, we may call him. Mr. Watt had directed his son's attention to the study of science on the Continent, and accompanied him, Thomas Cooper, the vice-president of the Manchester Society, and who afterwards became professor of chemistry in Columbia College, in America—was proceeded to Paris. But here, carried away by the passions of the time, he became a convert to the cause of liberty, he sympathized with the Girondists and Jacobins, and even took some open and avowed part in their earlier tumultuous agitations, in company with Cooper, and subsequently with Wordsworth the poet also. Southey has recorded, from the information of Mr. James Watt himself, that so highly was he at first regarded by the French leaders, that he was the means of preventing a duel between Danton and Robespierre. A more public exhibition of zeal in the cause which he espoused, in which Cooper also took part, was that of the celebration of the jubilee of the Declaration of the Rights of Man. The licence and excesses of the revolutionary parties however opened the eyes of the young enthusiast to the real nature of the principles he was supporting, and he then endeavored to mitigate as far as possible the violence which he foresaw he must in future deplore. This became eventually the cause of his quitting Paris and abandoning his French associates and their objects; for Robespierre, at the club of the Jacobins, inculminating that Cooper and his compatriots were emissaries of the English ministry, indignantly silenced his formidable antagonist from the tribune in a brief but impassioned harangue, delivered in excellent French, carrying with him the feelings of the rest of the room. Returning home he learned that he was no longer safe for a day, instantly left Paris, succeeded with difficulty in making his way to the south, and did not rest until he arrived in Italy.

Not long afterwards he returned to England, and in 1794, as already intimated, began to be actively engaged as a partner in the management and direction of the steam-engine factory at Soho, which necessarily withdrew him from political and also from scientific pursuits, strictly so called, and what he effected in the latter has almost escaped notice.

Mr. James Watt took a part in the progress of steam-navigation, especially as regarded the requisite adaptations in the construction of the engines, not unworthy of his name and of the reputation of the firm of which he became the leading partner. Mr. Henry Bell of Glasgow, who had in 1813 taken the enterprising step of himself trying, in Scotland, at his own risk and under his sole direction, an experiment similar to that which, in the hands of Fulton (whom he advised), had succeeded, so with the help of several steam-vessels propelled by engines of his own construction. Among these was the Caledonia, of 108 tons and 32-horse power, which was launched in 1815, but from defects inherent in the principle, had to be taken to Rotterdam for repairs and alterations. "After her return to the Thames in the spring of 1818," it is stated by Mr. Muirhead, to whose Memoir we are indebted for these particulars of the history of steam-navigation in this country, "Mr. James Watt may be considered as the author of several series of experiments with her on the river (the whole number of those experiments amounting to 250), which resulted in the adoption of many most material improvements in the construction and adaptation of marine engines, and in an immense, though gradual extension of the branch of the manufacture at Soho."

The marine engines manufactured there down to the year 1854, "were in number 319, of 17,438 nominal, or 55,314 real horse-power."

Some forty particulars of Mr. James Watt may be gleaned from the two later publications of Mr. Muirhead. He wrote, in 1823, the Memoir of his father in Macvey Napier's Supplement to the 'Encyclopaedia Britannica' (subsequently transferred, in substance, to the seventh edition of that work); and in 1846 he addressed a letter to Mr. Muirhead on his father's claims as to the composition of water; which is prefixed to the 'Correspondence' of the latter on that subject. The publication of his father's specifications, and the patents and documents relating to them was originally designed and, to a considerable extent, prepared by him; but, from the infirmities of age, confided prior to his decease to Mr. Muirhead, by whom it has been accomplished in the work already cited and described.
The Dover Railway traverses the beds of the Wealden between Red Hill and the branch-line to Timbrough Wells, exposing the Weald Clay and Upper Hastings Sands. The fossils of this group area follows:—

(Tenant, Stratigraphical List of British Fossils.)

**WEBSTER, THOMAS, F.R.S.** an eminent geologist, was one of the band of scientific men, who, with the late Professor Jameson, the late Leopold von Buch, and Alexander Humboldt, learned the rudiments of mineralogy and geology under the tuition of Werner at Freiberg, where he commenced his studies in 1786. He was long a distinguished and active member of the Geological Society of London, particularly in its earlier days; and was elected a Fellow of the Royal Society on the 9th of March 1786. From 1795 to 1796, and again in 1801, he was concerned, with the gentlemen mentioned below, in the exploration, on account of the government, of the deposits of gold which had been discovered at Crouchall Kinsella, in the county of Wicklow, in Ireland. An account of the discovery was given by John Lloyd, Esq., F.R.S., and a mineralogical account of the gold itself by Arthur Miller, Esq., both relating to Mr. Weaver, was published in the 'Philosophical Transactions' for 1796. A particular history of the proceedings of himself and his colleagues, in reference to the gold workings, was given by Mr. Weaver in his Memoir on the 'Geological Relation of the East of Ireland, inserted in the 'Transactions of the Geological Society,' first series, vol. v. He afterwards com-
no means lucrative. In 1608 he married his first wife, by whom he had two sons and two daughters, of whom only one son, Fletcher Webster, survived him. He is a naval officer of the port of Boston. In May 1513 Daniel Webster took his seat in congress and represented New Hampshire without interruption for nearly fifteen years. Placed by Mr. Clay, the speaker, on the committee of foreign affairs, he made his first speech in the house on the 10th of June, 1613, in moving a series of resolutions on the Berlin and Milan decrees. In 1620 he was appointed to a committee to examine the house, its furniture, library, and manuscripts, which were all destroyed. In August 1614 he was again returned as a representative to congress. From March to December 1615 he was busy engaging in the law firm of Plymouth, when he was transferred to the court of admiralty, to which he removed to Boston, where the causes for trial were of higher importance and the practice was more lucrative.

Mr. Webster retired from congress in 1617. He had purchased an estate of about 200 acres at Marshfield, thirty miles from Boston, and his time during the next six years was partly occupied with law business in Boston and partly with the cultivation of his estate. His favourite amusements were angling in the streams and fishing in the yard, and to private life he was again elected senator as he was also in 1624 and 1626. In 1627 his first wife died. In January 1628 he took his seat in the senate of the United States, having been elected by the legislature of Massachusetts.

He was a candidate for the dignity of president in 1682, but received no votes. In the spring of 1683 he visited Europe for the first and only time in his life, and made a highly tour through England, Scotland, and France. When General Harrison became president in 1681, he was appointed to the office of British army counsel for the states, and in 1682 he was elected chairman of the committee of correspondence. In 1684 he was nominated to the presidency, but was un-electable.

On the death of General Taylor in July 1686, he was re-elected as a member of the court of admiralty, and continued to perform the duties of that high office till his death, which occurred October 24, 1686, at his country residence, Marshfield.

Daniel Webster, as a statesman, an orator, and a lawyer, was one of the greatest men that the United States of America have produced. As a statesman his principles were founded on comprehensive views and a wide range of information, legal, constitutional, and historical, but during his later years he was more a deliberator than an orator. Few men were less disposed to a presiding state than he. He was a decided Federalist. He expressed his belief that if ever the union of the States should be dissolved, the internal peace, the vigorous growth, the prosperity of the States, and the welfare of the inhabitants, would be blissful for ever; and that while the Union endures, all else of trial and calamity which may befall the nation may be remedied or borne. He was undoubtedly the greatest American orator of his day. His power of fixing the attention and producing an overwhelming effect on a deliberative assembly was unequalled. His style was generally argumentative and solid, never deficient of imagery where suitable, but never flowery.

The Works of Daniel Webster,' 6 vols., 8vo, Boston, 1861, consist of his speeches in congress, at the bar, and at public meetings, his correspondence, a few letters, and a Biography by Edward Everett. WELLS.

WEIGHTS AND MEASURES. [Standard, s. 2.]

WEISSE. [Mineralogy, s. 1.]

WELLINGTON, DUKE OF. Arthur Wellesley was born on the 1st of May, 1769, at Degan, Castle, in the county of Meath, Ireland; but in the registry of St. Peter's Church, Dublin, it is recorded that "Arthur, son of the Right Honorable Earl and Countess of Mornington, was born on the 30th of April, 1769." It is probable therefore that he was born in March, at Mornington House, Dublin, the town residence of his parents. After the battle of Waterloo he kept his birthday on the 16th of June, the anniversary of that important victory. He was the third son of the first Earl of Mornington. [Mornington, Eazor.]

The family name was originally Wesley, derived from the Rev. Dr. Samuel Wesley, who was a member of the Wesleyan family. He was a consecrated clergyman and a resident of the village of Wesley, near Northampton.

In 1777, when the name was altered to Wellesley by the first Duke of Wellington, the estate of Wesley was purchased by Sir Henry Wellesley, a grandson of the first Earl. Sir Henry Wellesley was one of the first and most influential members of the family, and was the founder of the celebrated family line. He was the first to adopt the name of Wellesley, and his descendants have continued to bear it ever since.

The first Duke of Wellington was a great soldier, and a statesman of great ability. He was a member of the British parliament, and served in a number of important positions, including Secretary of State for War and the Colonies. He was also a member of the British cabinet, and served as Prime Minister of the United Kingdom for a number of years. He was a great admirer of the British empire, and was a strong supporter of the British navy. He was also a great supporter of the British army, and was a strong advocate of the British military establishment.

The first Duke of Wellington was a great hero of the Napoleonic Wars, and is considered one of the greatest military commanders in history. He was a master of the art of war, and was a great strategist and tactician. He was a great lover of the British army, and was a strong supporter of the British military establishment.

The first Duke of Wellington was a great writer, and was the author of a number of important works. He was a great admirer of the British empire, and was a strong supporter of the British navy. He was also a great supporter of the British army, and was a strong advocate of the British military establishment.

The first Duke of Wellington was a great statesman, and was a member of the British parliament for a number of years. He was a great admirer of the British empire, and was a strong supporter of the British navy. He was also a great supporter of the British army, and was a strong advocate of the British military establishment.
enter into negotiations, and was evidently trying to gain time, the allied British and native army was ordered to advance into Mysore, which they entered early in March 1799. On the 27th an engagement took place, in which the left wing of the allies, under Colonel Wellesley, routed a body of Tippoo's choice infantry. The army then advanced to Seringapatam, Tippoo's capital, and Colonel Wellesley employed to dislodge the enemy from some strong posts in front of the town, which he executed in gallant style, and with little loss. The fortress of Seringapatam was invested, and the 4th of May the place was stormed by a party under General Baird. After the storming was over, and the confusion began to subside, General Baird desired to be relieved, and Colonel Wellesley ordered him to take up his position on the left of the place. By his exertions and firmness he succeeded in stopping the plunder within the town. Tippoo Saib was slain.

In July 1799 Colonel Wellesley was appointed governor of Seringapatam, then the capital of Mysore. During several years that he held almost vice-regal command in Mysore he was fully occupied in organizing the civil and military administration of the country, and in the execution of this task he improved his natural talents for business, military and civil, and gave an example that quickened the decision of character which have characterized him throughout the whole course of his military career. From the beginning also he paid particular attention to the wants of his soldiers, provided for the supply of provisions, to the management of the hospitals, and to the comfort of the Commissariat and Quartersmaster-General's department, which constitute half the business of an army, and, to use his own words, if neglected, "misfortune and disgrace will be the inevitable consequence." He was always true to his word, and his humanity, and the strict discipline that he maintained among the troops, he acquired the confidence and respect of the native population of Seringapatam.

He was employed in Mysore he was obliged to take the field against one of those revolts that prevale in various parts of India, named Dhondia Waug, who had got together 5000 horsemen, part of Tippoo's dissipated cavalry, and partly from other predatory hands, and who styled himself "King of the Two Worlds." After marching about a month, after having chased of two months, came up with him on the 10th of September 1800, immediately attacked him, and put his army to the rout by a single charge, in resisting which Dhondia himself was slain. In December of the same year Colonel Wellesley was appointed by the governor-general in council to command a body of about 8000 troops asembled at Trincomalee, in the island of Ceylon, for foreign service, and he accyrly proceeded from Mysore to Trincomalee. The expedition was intended either for Batavie or the west end of France. Meantime he set about directing 3000 men to be sent to the Red Sea to act against the French in Upper Egypt, whilst an expedition from Europe, under Sir Ralph Abercorn, was attacking Lower Egypt. The Madras army sent Colonel Wellesley a copy of the despatches from home, and as he knew that his brother, the governor-general, when he ordered the assembling of the force at Trincomalee, had some expectation of its being required for Egypt, Colonel Wellesley, upon his own responsibility, moved at once the whole force to Bombey, where it could be supplied with provisions and other necessary in time to sail to the Red Sea, and where he would be ready to receive final orders from the governor-general. He arrived there about the middle of February 1801, and arrived at Bombey about the middle of March of that year. The governor-general had appointed General Baird to command the Egyptian expedition, leaving to his brother the choice of going under him as second in command, or retaining his own command in Mysore. When Lord Mornington learnt that Colonel Wellesley was at Bombey with the whole Trincomalee force, he could not disapprove of this movement, as he had himself intended to send to the Red Sea a larger body of troops than that which was left at home despatches, but still he thought it ought not to be done without the consent of the commander-in-chief, and required an official explanation of the grounds and motives which had induced his brother thus to act upon his own judgment, without waiting for orders. Colonel Wellesley was not surprised at his brother's remonstrance. General Baird, on 23rd March, 1801 ("Dispatches," vol. 1.) He intended to proceed to the Red Sea, and to have served under General Baird; but on the 26th of March he was seized with fever, and soon afterwards returned to his government in Mysore.

Before leaving Bombay he transmitted to General Baird a memorandum which he had written concerning the operations in the Red Sea, evincing the research and reflection which he had bestowed on his anticipated command.

Colonel Wellesley made an inspection in Mysore of nearly two years. He was raised to the rank of Major-General in April 1802, and in February 1803 he was appointed to command a force intended to march into the Maharrat territory.

On the land war waged between the Mahratta chiefs Holkar and Scindia. The Peishwa, the nominal head of the Mahratta confederation, was looked upon as an instrument in the hands of the strongest. Dowlat Rao Scindia, who ruled the country of Scindia, was a man of great ability and cunning, and artillery, which had been formed by his father, with the assistance of M. de Boigne, a native of Savoy, and was now under the direction of a French officer of the name of Perron. Scindia exercised paramount influence over the Peishwa at Poona. Holkar, another ambitious chief, who had long been at variance with Scindia, suddenly crossed the Nerbudda and marched with a large cavalry force on Poona, which he entered after defeating the combined army of Scindia and the Peishwa. The Peishwa fled to scindia, and Holkar sent a deputation, which Scindia succeeded in subduing, whilst Holkar placed one of his relations on the seat of power at Poona.

The Madras army, under Lieutenant-General Stuart, was ordered to advance into the Mahratta territory for the purpose of making despatches, and Major-General Wellesley was appointed to command a select corps in advance, with which he marched rapidly upon Poona. Having received information on the road that Holkar's army was moving towards the place where he was then encamped, he ordered his cavalry to be put into the field, and, advancing a force of 60 miles in 30 hours, reached Poona on the 20th of April, and thus saved the town. Holkar's people retired without fighting, and in the following month the Peishwa re-entered his capital. Scindia however, being joined by a powerful Mahratta chief, was together in the field making hostile demonstrations against the English and their ally the Nizam, and they were understood to be in correspondence with Puttan, who was joining him in a projected movement against the Mahratta affairs, which was yet more dangerous at a moment when the peace of Amiens the French had just recovered their Indian possessions, the governor-general appointed General Wellesley to the chief command of all the British and allied troops serving in the territories of the Peishwa and the Nizam, with full power to direct all the political affairs of the British government in the same district. (Dispatches,' Fort William, 26th and 27th of June, vol. ii.) The force at his command consisted of about 10,000 troops of all arms, 2000 horse, and 600 guns, and was in the field for 74th Foot. After some fruitless negotiations with Scindia, General Wellesley marched from Poona to the north, and took by escalade the town of Ahmednuggur, which was surrendered to him. He then crossed the river Godavry, and entered Aurungabad on the 28th. The enemy manifested an intention to cross the river to the eastward and steal a march upon Hyderabad, but were prevented by General Wellesley marching along the left flank of the river, and placing himself between them and that city. On the 12th of September the British general was encamped 20 miles north of the Godavry. Colonel Stevenson, with the Nizam's auxiliary force, was at some distance from him. Scindia, who had a large mass of irreducible parties, was no longer able to support the British discipline, and only thought of carrying on a predatory warfare.

About the middle of September, General Wellesley learnt that Scindia had been reinforced by 16 battalions of infantry commanded by French officers, and a large train of artillery, and that the whole of his force was assembled near the banks of the small river Kaina. On the 21st of September General Wellesley had a conference with Colonel Stevenson, on which it was agreed to take the offensive, and to march upon the town of Beed, the capital of the Mahratta country.

The General and the Colonel advanced by two parallel routes round the hills, so as to fall at the same time upon the enemy. General Wellesley on the 33rd received a report that the enemy, after retiring, had crossed the river, and then retired by the morning with their cavalry, and that the infantry were about to follow, but were still in camp at the distance of about six miles. General Wellesley determined to march upon the infantry, and engage it at once. He sent a messenger to
Colonel Stevenson, then about eight miles on his left, to inform him of his intentions, and directing his advance. He moved forward with the 19th Light Dragoons and three regiments of native cavalry to reconnoitre. The infantry, consisting of two British and five native battalions, followed. After a march of about four miles he saw from an elevated plain not only the infantry, but the whole Mahratta force, consisting of infantry, cavalry, and artillery; the right, consisting of the cavalry, was about 10,000 men, and the left, consisting of the infantry, was about 30,000 men, and the rear was still thicker. The British force was entirely unprepared, when the whole Mahratta line retired in disorder, leaving 38 pieces of cannon and all their ammunitions in the hands of the British. The British cavalry pursued the enemy for several miles, taking many elephants, camels, and many baggage; but, after four hours' hard fighting, the British were driven back by the strong force of the enemy, and this exploit concluded the campaign. The Raja of Barar now used for peace, and General Wellesley drew up the conditions of the treaty, by which the Raja ceded to the Company the province of Cuttack with the district of Balsore, and dismissed his European officers. Scindia was glad to follow the example, and on the 30th of December he signed a treaty of peace, by which he ceded to the Company all the country between the Jumna and the Ganges, besides numerous forts. In February 1804, General Wellesley crossed the Ganges to take up his residence in Benares. The young Mahratta princes who had just ascended the throne were fond of universal freedom-party, and, as carrying devastation through the land. The officers of the army of the Deccan presented him with a service of plate of the value of 2000 guineas, with the inscription, "Battle of Assaye, 6th September 1803."

On the 8th of June 1804, General Wellesley broke up the army in the Deccan, in pursuance of orders of the governor-general, and the following month he returned to Seringapatam, where he received from the native inhabitants an affecting address, in which they "implored the God of their fathers to crown all the cares of their constant prayer, whenever greater affairs might call them forth to bestow on him health, glory, and happiness." (Dispatches, vol. iii., p. 493.)

In July 1806, the British army was called to Calcutta to assist in military deliberations. Several important memoirs on the political and military affairs of India, which are given in the third volume of the Dispatches, were written by him about this period. In November of the same year, he left Calcutta for Madras, where he remained till April 1807. In February 1805 he again repaired to Madras, and obtained leave to return to England. About the same time his appointment by the king to be a Knight Companion of the Order of the Bath was published in India, and published in the general orders; and in the following March the thanks of both Houses of Parliament to Major-General Wellesley, for his services, were likewise published in the general orders in India. On the 10th of March 1805 Sir Arthur Wellesley sailed from Madras.

General Sir Arthur Wellesley landed in England in September 1805. In November of the same year he was sent to Hanover in command of a brigade in the expedition under Lord Cathcart, which was intended to make a diversion against the French whilst the army of the Rhine was engaged at Danube against Austria and Russia. The tergiversation of the Prussian cabinet, and the disastrous battle of Austerlitz (December 1805), disconcerted the plans of the allies, and the English returned from Hanover to England in February 1806, without having seen any active service. Sir Arthur Wellesley was now appointed to the command of a brigade of infantry stationed at Hastings. In January 1806, when the news was received of the death of the Marquis of Cornwallis, he was made a Peer of the Empire, and was appointed Governor-General of India. On the 10th of April 1806, he married Lady Catharine Pakenham, third daughter of the Earl of Longford. In that year he was elected member for the borough of Rye, and from his seat in the House of Commons he defended the administration of Lord Hardwicke, which he regarded as "the best of any ministry for the last 25 years." On the 18th of May 1807 Sir Arthur Wellesley was appointed secretary for Ireland, the Duke of Richmond being lord-lieutenant of Ireland, and in that capacity was sworn a member of his Majesty's Privy Council. In August of the same year he was appointed Governor-General of the United Provinces of the North-west of India, and in 1810 of Copenhagen, under Lord Cathcart and Admiral Gambier. On the 30th of August General Wellesley's division attacked the Dutch troops at Koge, carried their entrenched camp, and captured the town of Koge, when they took a large military store and nearly 1300 prisoners. This was the occasion of any importance which took place by land. The bombardment of Copenhagen having induced the Crown Prince of Denmark to listen to terms, General Wellesley was appointed
by Lord Castlereagh, together with Lieutenant-Colonel Murray and Sir Home Popham, captain of the fleet, to draw up the articles of the capitulation, which were agreed to by the Dauphin on the 7th of September, and by which the Danish fleet and naval stores were delivered to the British government till the peace. General Wellesley returned to England with the expedition, and resumed his duties as secretary for Ireland. In the following February (1808) he received in his place in the House of Commons, the thanks of that House for his important share in the success of the expedition, and was appointed commander-in-chief by the legislature, but he was deprived of the assistance of the Danish fleet, upon which he had reckoned in his plans against England.

In the spring of 1808 a military force was assembled at Cork, intended, it was believed, to act against the Spanish colonies of South America, Spain, and through French influence, at war with England. But the invasion of Portugal and Spain by Napoleon, occurring about the same time, gave a new destination to the English expedition. The people of Spain declared against the invaders, and sent to England to ask for assistance. Juntas, or local governments, were formed, and peace was proclaimed between Spain and England. The main strength of the Spanish patriots appeared to be in the north, in the mountainous provinces of Aragon and Catalonia, which were naturalistich to the French, and the deputies who came to England from those provinces requested the employment of an English auxiliary force to effect a diversion by landing on some point of the Spanish coast, and Sir Arthur Wellesley, who had been promoted to the rank of Lieutenant-General, April 25, 1808, was appointed in the following June to the command of the force intended for the Peninsula, consisting of about 9000 infantry and a regiment of light dragoons, with the promise of a reinforcement within a short time. The expedition formed altogether a respectable military force, but the importance of the occasion waranted exertions even greater than these, for the Spanish peninsula had now become the field on which the great question was to be decided. The province of Portugal was to act as a buffer between Spain and Europe, and dictate to all other states, Great Britain included.

Sir Arthur Wellesley landed at Corunna July 20, 1808. The Junta of Galicia asked for nothing but arms and money. They declared an insurrection in case of British auxiliary forces, but they advised General Wellesley to land in Portugal, to rescue that kingdom from the French grasp, and thus to open a ready communication between the north and south of Spain. This was in accordance with Sir Arthur Wellesley's own views, and the general instructions that he had from home. He accordingly sailed on to Oporto, which town had already risen against the French; and there he found the war-like bishop, who was at the head of the insurrection, and had gathered together 5000 men indifferently armed and equipped. He also landed at 6000 men. These French were quartered on the coast, but retired to Lisbon. On the 30th of July, he anchored in Mondego Bay, which he fixed upon for the landing of the expedition. The landing took place on the 1st of August, near the small town of Figuerias, on the south bank of the Mondego. The number of troops landed was about 9000. On the 8th Major-General Spencer joined him from Cádis with about 4000 more.

The French force in Portugal at the time, under Junot, consisted of 15,000 men, in winter quarters, conducting the garrisons of Almeida, Elvas, Peniche, Setubal, and other places, there remained about 14,000 men for the defence of Lisbon. Their communications were cut off from their countrymen in Spain, for, since the surrender of General Dupont, the Spanish patriots were masters of Andalucia and Estremadura, and in Old Castile the French troops under Bes-teres had not advanced westward further than Benavente, being observed by the Spanish army of Galicia. Although the French were now in the middle of winter, they retired to the Ebro. A clear stage therefore was left for the contest in Portugal between Wellesley and Junot, whose respective disposable forces were nearly equal, the French however having the advantage of a considerable body of cavalry in support of their line of communications.

On the 9th of August the English began their march southward. The advanced guard entered the town of Leiria on the 10th, where it found the Portuguese force of 6000 men under General Freire, who, having appropriated to the wants of his men the stores which, by an agreement between the junta of Oporto and Sir Arthur Wellesley, were intended for the English, further demanded that his corps should henceforth be furnished with provisions by the English commissioner. Sir Arthur Wellesley, however, informed General Freire that his corps was by resolution of the junta of Oporto, and Wellesley declined to comply. Freire then refused to advance with the English, but remained behind at Leiria, and was with difficulty prevailed upon to allow about 1000 of his men to join Sir Arthur. On the 14th the English, under the command of Sir John Caldas, following the road to Torres Vedras, which runs parallel to the sea-coast. It was near Rolica, about ten miles beyond Caldas, that the first engagement took place.

When the Spanish had risen against the invaders, the spirit of resistance spread to Portugal, the natives of which country had equal motives for being dissatisfied with the French rule. The French had with their army several Spanish regiments, which were scattered about the country in the several garrisons. The Spanish troops which were at Oporto, forming the principal part of that garrison, hearing of the news from Spain, revolted against the French commandant. The English commander then sent for a few French soldiers that he had with him, and set off with their prisoners for Spain, leaving the Portuguese at liberty to act as they pleased. A junta was then formed, with the bishop at their head, and the whole of the provinces north of the Donro rose against the French. The insurrection spread southward into Beira. In the south the people of Algarve rose, and those of Alemtejo followed their example, being supported by a body of Portuguese, which, at the time of the engagement, were on their way to join the insurrection in that quarter.

The French General Loison, who had been sent to repress the insurgents in the north, was quickly recalled by Junot and sent into Alemtejo. He entered Évora after a desperate action, in which the town was given up to indiscriminate massacre. General Margarow executed like vengeance at Leiria, sparing neither age nor sex. Similar scenes took place at Guarda in the north, and at Beja and Villevolges in the south. In the town of however from Parno, the English also losing their own men daily, for the peasants were always hovering about their line of march, ready to cut off stragglers and intercept the communications. The whole kingdom," observed Sir Arthur Wellesley in one of his first despatches after landing in Mondego Bay, "in the exclusion of the neighbourhood of Lisboa, is in a state of insurrection against the French. Their means of resistance are however less powerful than those of the Spaniards. The Portuguese troops were been reduced to 1200 men, of whom 500 are stationed off to Brazil, and their arsenals are pillaged or in the power of the enemy. Their revolt, under the circumstances in which it has take place, is still more extraordinary than that of the Spanish nation. They have lost the cases of the nation, and the strength of the position of the French near Lisbon. On the 30th of July, he anchored in Mondego Bay, which he fixed upon for the landing of the expedition. The landing took place on the 1st of August, near the small town of Figuerias, on the south bank of the Mondego. The number of troops landed was about 9000. On the 8th Major-General Spencer joined him from Cádis with about 4000 more.

The French force in Portugal at the time, under Junot, consisted of 15,000 men, in winter quarters, conducting the garrisons of Almeida, Elvas, Peniche, Setubal, and other places, there remained about 14,000 men for the defence of Lisbon. Their communications were cut off from their countrymen in Spain, for, since the surrender of General Dupont, the Spanish patriots were masters of Andalucia and Estremadura, and in Old Castile the French troops under Bes-teres had not advanced westward further than Benavente, being observed by the Spanish army of Galicia. Although the French were now in the middle of winter, they retired to the Ebro. A clear stage therefore was left for the contest in Portugal between Wellesley and Junot, whose respective disposable forces were nearly equal, the French however having the advantage of a considerable body of cavalry in support of their line of communications.

On the 9th of August the English began their march southward. The advanced guard entered the town of Leiria on the 10th, where it found the Portuguese force of 6000
Manny's right, and thus watch the approach of Loison; and be centre, which was the column of attack, to march along
valley to the front of Laborde's position. The French, after a gallant defence, were obliged to retire, which they did in good order, being protected by their cavalry. They withdrew to Torres Vedras, where they were joined by Loison's corps. The loss of the French in the engage-
ment was estimated at about 600 killed and wounded, besides three pieces of cannon; that of the British was 450. It must be observed here, once for all, that the
offensive of the French throughout the war were never accu-
ately known, as they published no returns, whilst the British
made weekly returns. The commanders and the respective officers in command of regiments after a battle, were always published in the 'Gazette.'

On the 10th of August General Wellesley advanced to Estremoz, keeping along the coast-road leading to it. In the 10th he moved to Vimiero, where he was joined next day by Generals Anstruther and Auckland, with two brigades just arrived on the coast from England, and which raised his force to about 17,000 British, besides 1600 Portuguese. At the same time, General Wellesley was superseded in the chief command by Lieutenant-General Sir Harry Burrard, who arrived from England. The govern-
ment at home had determined, in consequence of the prop-
lions appearing of affairs in the Peninsula, to have there an army on the spot, and a force offered to the French and
ordered the corps of Lieutenant-General Sir John Moore, which had just returned from a fruitless expedition to the Baltic, to proceed to Portugal; and they gave the chief command of the army to Lieutenant-General Sir Hew Dalrymple, governor of Lisbon, Sir John Moore, respectively, was restored to the chief command; and Lieutenant-Generals Sir John Moore, Sir Arthur Wellesley, the Hon. John Hope, Lord Paget, and MacKenzie Fraser, to command respectively divisions of the army.

Sir Harry Burrard arrived in a frigate in (Maceia Bay, near Vimiero, on the evening of the 20th, and General Wellesley immediately went on board, and reported to him his situation of the army, and his own intended plan of action. He did not believe the enemy was at Mafra, and thus turn the strong position which De Laborde and Loison had taken at Torres Vedras. By this mea-
sure he would oblige the French either to give battle or retreat to Lisbon under great disadvantages. Sir Harry Burrard how-
ever decided not to advance, nor, under the threat of the
reinforcements under Sir John Moore. But the enemy in the meantime was bringing the question to a speedy
issue.

Next, having joined De Laborde and Loison at Torres Vedras with all his force, estimated at about 14,000 men, of whom 1600 were cavalry, attacked the English in the position at Vimiero early in the morning of the 21st of August. The principal attack was made upon the British centre and left, with the intention of having him surrouned, and this was done, of times, of driving the English into the sea, which was closed in their rear. The attack was made with great bravery and steadiness, but was as gallantly repulsed by the British; it was repeated by General Kellerman at the head of the French reserve, which was also repulsed; and the French, being charged by the bayonets, withdrew on all points in confusion, leaving many prisoners, among them a general officer, and 14 cannon, with ammunition, &c., in the hands of the British. The loss of the French in killed and wounded was estimated at about 900, of which 200 was British. It was 730. Sir Harry Burrard landed, and was present in the field during part of the engagement, but he declined assuming the command, or in any way interfering with General Wellesley's dispositions, till the enemy was repulsed. Towards the close of the action, when the French were seen retiring in confusion, General Wellesley wished to follow up his victory; General Ferguson on the left was actually close upon the retreating enemy, and if General Hill and the advanced guard had not had a desperate struggle, they would have reached it before the French, who would have been cut off from Lisbon, and perhaps obliged to lay down their arms. Such was Sir Arthur's view; but Sir Harry would not move any farther, especially on account of the superiority of the French cavalry. General Ferguson was ordered to desist from pur-
suit, and the French officers were thus enabled to rally their men, and make good their retreat to Torres Vedras.

On the 30th of August Sir Hew Dalrymple, the com-
mander-in-chief, landed in Maceia Bay, and assumed the command. In the course of the day General Kellerman was advanced with a flag of truce on the part of Junot to propose an armistice, preparatory to entering into negotiation for the evacuation of Portugal by the French. The terms were discussed between General Kellerman and Sir Hew Dal-
rymple, who in the end directed General Wellesley to sign the armistice. Among the articles there were various by which it was judged the terms of the final convention by stipulating that the French army should not "in any case" be considered as prisoners of war, and that all the individuals composing it should be carried to France with arms and baggage, and that of every officer and soldier, nothing should be withheld." This, of course, would include the church plate and other public and private property which the French had taken either at Lisbon or in the various towns which they had sacked in consequence of the
invasion, to which they had been admitted. General Wellesley did not "entirely approve of the manner in which the instrument was worded;" but the articles being laid before the commander-in-chief, were signed by him that evening. The armistice however was made subject to the approbation of the Admiral, Sir Charles Cotton; and as one article of it stipulated that the Russian fleet in the Tagus, under Admiral Sinivain, should enjoy all the advantages of a neutral port, Sir Charles objected to this, and the convention was therefore suspended. In the evening Russian admiral. On the 25th Sir Hew Dalrymple signified to Junot that the armistice would be at an end on the 28th at noon, unless a convention for the evacuation of Portugal by the French should be agreed upon before that day. In the mean time, Sir Hew Dalrymple made his head-quarters at Vimiero to Renalhal, near Torres Vedras, within the boundaries stipulated by the armistice. Sir John Moore had also arrived in Maceia Bay, and his troops were about being landed. It is important, in considering the necessity of coming to terms, commissioned General Kellerman, who forwarded, Colonel Murray, quarrermaster-general to the British army, about the final convention. The favourable moment for pushing upon the French was now past; and if they were to come over in force, they might either defend themselves within Lisbon, or cross the Tagus to Elvas, which, being a place regularly fortified, would have required a long siege, during which the British army could not have been made available in Spain. (Inquisit. iv., p. 130.) General Wellesley, on the 27th, Sir Hew Dalrymple a memorandum for Colonel Murray, suggesting, among other things, a separate agreement with the Russian admiral, and the propriety of devising some scheme which should give up the church plate which they had seized. On the 30th the convention for the evacuation of
convention was brought to the British head-quarters at Torres Vedras, and, being laid before a meeting of general officers, several alterations were made, and the form so altered was presented to Junot at last moment, with the concurrence of General Wellington, with the omission of several of the alterations, and was ratified by Sir Hew Dalrymple on the 31st. Sir Arthur Wellesley was not present at the final ratification, being at Sobral with his division. This document has become known by the name of the Convention of Cintra, though it was arranged at Lisbon, and finally ratified at Torres Vedras. The article which gave most offence was that by which the French, under the name of baggage, were allowed to carry off much of the plunder of Portugal. Some limits however were put to this by a clause corresponding with General Bercourt at the head, to superintend the strict execution of the terms of the convention. Through the exertions of the commissioners the spoils of the Museum and the Royal Library were restored, together with the money taken from the public treasury. With regard to the Russian fleet, it was agreed that the ships should be held as a pledge by Great Britain during the war, and that the crews should be conveyed home in British ships.

The French evacuation took place in the month of September, and the British troops took possession of the forts of Lisbon in the name of the Prince Regent of Portugal. The whole country being now free from the enemy, a council of regency was appointed, of which the active Bishop of Oporto was a member. The junta of the Portuguese in general was manifested in the most unequivocal manner. But in England the terms of the convention were the subject of severe and loud censure, and the government appointed a board of in-
quiry to examine into the matter. Sir Hew Dalrymple and
Sir Harry Burrard were recalled in order to be examined by the Board, as well as Sir Arthur Wellesley, who had already asked and obtained leave to return to England. The court sat in the month of November, and, after a long examination, reported that, the Convention of Chiutra having been productive of great advantages to Portugal, to the army and navy, and to the general service, the court was of opinion that no further proceeding was necessarily necessary on the subject, "because, however some of us may differ in our sentiments respecting the fitness of the convention in the relative situation of the two armies, it is our unanimous declaration that unquestionable zeal and firmness appear thoroughly possessed by them." The General Board of General Sir Hew Dalrymple, Sir Harry Burrard, and Sir Arthur Wellesley, as well as that the ardour and gallantry of the rest of the officers and soldiers on every occasion during this expedition have done honour to the troops and reflected lustre on your Majesty's arm." The king adopted the opinion of the board.

Sir Arthur Wellesley's employment in the Peninsula being now terminated, he resumed the duties of his office as Chief Secretary for Ireland, whither he proceeded in the month of December. Parliament having re-assembled in January 1809, he returned to London to resume his seat in the House of Commons. On the 27th of January he received, through the Speaker, the thanks of the House for his distingushed conduct in the province of Galicia, and the House of Lords passed resolutions to the same effect, which were communicated to Sir Arthur by the Lord Chancellor.

Campaign of 1809.—Napoleon, with an army of more than 25,000 men, having burst through the lines in line and routed the troops, forced in person the strong pass of the Somosierra on the 30th of November 1808, and four days afterwards was in possession of Madrid. Meantime, Buonaparte, with an overwhelming force, had been sent against Sir John Moore, who had advanced into Spain as far as Salamanca. This movement was followed by the disastrous retreat of the small army under Sir John Moore, the battle of Corunna, January 16, 1809, in which the heroic commander was slain, and the disbanding of the British forces for England. The French, following up their success, spread over Leon and Estremadura to the borders of Portugal, and Soult, having overrun Galicia, marched into the northern Portuguese provinces, and carried Oporto by storm against the native troops. The small British force which had been left in Portugal when Sir John Moore advanced into Spain was concentrated by General Sir John Cradock for the defence of Lisbon. The unfavourable turn of affairs in Spain induced the British government to make another effort to assist Sir John Moore, and to send reinforcements to the Spaniards in their momentous struggle. Sir Arthur Wellesley, having previously resigned his office of Secretary for Ireland as well as his seat in parliament, was sent to Portugal to assume the chief command of the British forces in the Peninsula; and arrived there, having left his staff with his staff. He was followed by reinforcements of infantry and several regiments of cavalry. These, together with the Portuguese regulars under General Beresford, who the Prince Regent had appointed to the chief command of his army, enabled him to bring into the field a force of about 25,000 men, with which he marched at the end of April to dislodge Soult from Oporto, leaving a division under General Mackenzie on the Tagus to guard the eastern frontier. At the same time, the French force of General Victor was stationed near Merida, in Spanish Estremadura. The army under General Wellesley, having assembled at Coimbra, moved on the 9th of May in the direction of Oporto, and drove back the French troops, which had advanced south of the Douro. On the 11th of May by night, and supplied the southern bank of that river opposite the city of Oporto. The French had destroyed the bridges and removed the boats to their own side, and Soult was preparing to retire to Galicia.

General Wellesley sent a brigade under General Murray to pass the river about four miles above Oporto, whilst the bridge of Gares was directed to cross the river at the suburb of Villavermude, and the main body under the commander-in-chief passed over the Douro in about five Portuguese boats that they could find. The Douro at that spot is very rapid, and nearly three hundred yards wide. About ten o'clock in the morning of the 15th of May, two hosts having been discovered, General Fretaz with three companies of the Buffs crossed the river, and got possession of an unfinished building on the Oporto side, called the Seminaria. The French in Oporto were taken by surprise and, alarmed, and marched out to oppose the Seminaria, but, before they could dislodge the first party that had landed, General Hill crossed with fresh troops, and, pursued by the British artillery from the southern bank, and the Galicia, and driven back General Sherbrooke with the Guards crossed lower down into the very town of Oporto, amidst the acclamations of the inhabitants, and charged the French through the streets. Meanwhile the head of Murray's column, which had crossed at the time when the French first showed their retreat, which was effected in the greatest confusion. He left behind his sick and wounded and many prisoners, besides artillery and ammunition, and retired by Amarante with the view of passing into Spain through Trueba-Montes; but finding that Lobain had to hold the possession of Amarante, which was taken possession of by the Portuguese, he marched by Guimarães, Braga, Salamanca, and Montalegre, into Galicia. In this disastrous retreat the French were obliged to destroy in Januari of the artillery and part of their baggage, and the road was strewed with dead horses and mules, and French soldiers, many of whom were put to death by the passers-by before the advanced guard of the British could save them.

Sir Arthur Wellesley pursued the French as far as Montalegre, and, having driven them out of Portugal, retraced his steps to the south. The passage of the bridge and the capture of Almeida and Bragança were regarded as the most favourable circumstances. The English lost in the attack of Oporto only 23 killed and 69 wounded.

On taking possession of Oporto, General Wellesley issued a proclamation, stating that the inhabitants to respect the French wounded and prisoners, and he wrote to Marshal Soult to request him to send some French medical officers to take care of their sick and wounded, as he did not wish to treat them as prisoners.

The mention that Sir Arthur Wellesley was now turned towards Spain. It was necessary to strike a blow in the country, and the present occasion appeared favourable. The condition of the national cause of Spain had improved since Napoleon had left her; for the general had individually the same means that he had at his disposal, and there was not a sufficient bond of war amongst them all to make them act in concert. Each had a separate command over a large division of the country, and each had his separate interest. Soult, under the orders of Napoleon, who had been established in Madrid as king of Spain, had little or no control over them, and had not himself sufficient military skill to direct their movements. Each marshal, therefore, and there were five or six in all, had his own command, his own policy, his own plans, his own tactics and his own discipline. Marshal Victor, Duke of Bellena, commanded the first corps in Estremadura, near the borders of Portugal, having about 35,000 men, of whom however only 20,000 were under arms. General Sebastián commanded the fourth corps in La Mancha, which mustered about 20,000 men under arms. A division of reserve under Desoles stationed at Madrid, together with King Joseph's guards, amounted to about 15,000 men. Keilermann's army near Bollena, with some of the Spanish forces of Leon and Asturias, comprised about 10,000 more. All the above troops, amounting to about 60,000 disposable men, were considered to be immediately under King Joseph in the protection of Madrid and of Central Spain, and also under the orders of Marshal Victor. The corps of Soult and Tages and the Guadarrama. Soult had a distinct command. He had mainly to occupy the northern provinces of Spain and to act through them against Portugal. He had in front of him about 20,000 men under arms; the fifth, or Mortier's corps, amounting to 16,000; and Ney, with the sixth corps about 15,000. Soult's force in all was about 58,000 men on the field. These were the two French armies with which Soult had to contend, and in which he was likely to fall into collision. Besides these there were in Eastern Spain the third and seventh corps, making together about 50,000 men, under Buchs and Augereau, who were pretty much employed in Aragon and Catalonia; and 35,000 men var
the Puertó de Baños, upon Piasencía, in the rear of the British. General Wellesley had charged de Cuesta to guard the
mountain-pass to La Raschana. He had also sent only 600 men thither, a force which of course proved insufficient to arrest Soulí's march. General Wellesley did not know that Ney had unexpectedly evacuated Galicia, and was also advancing from Asturias upon the British left. Mortier also, with his cavalry corps, was moving forward; so that there were more than 60,000 fighting men of the enemy behind the mountains of Piasencía, ready to act on the left flank and rear of the British, who had besides 60,000 more in front of their headquarters. The British force in the field did not exceed 40,000. There were still 6000 of Soulí's men on their march from Lisbon to join the army, but they did not arrive till after the battle. The Spanish army of Cuesta mustered about 24,000 men, such as they were. The Portuguese regiments, under Besseres, had rendezvous to guard the north-east frontier of Portugal, towards Almeida. It had been previously agreed between General Wellesley, Cuesta, and the Spanish Supreme Junta, or Central Government, that General Venegas, who was at the head of the Spanish army of Andalucia, consisting of about 25,000 men, should march through La Mancha upon Madrid, while Wellesley and Cuesta were advancing by the valley of the Tagus. Venegas did advance through La Mancha, but it seems that he received no communication from the Junta whilst the effect of slackening his march; he however made his appearance at last towards Aranjuez and Toledo, and it was his approach on that side which induced King Joseph to engage Wellesley and Cuesta, in order to save Madrid from the hands of the Allies. When the French army had been dispersed over a great extent of territory, and Soulí's arrival at Piasencía would have obliged the English to retire precipitately. But King Joseph fearing that Venegas from the south, and Sir Robert Wilson, who, with the Lusitanian Legion, was hovering in the neighbourhood of the Allies, was marching with 20,000 men towards Talavera, Cuesta fell back with him upon the position of Talavera, where there was good ground for defence. He placed the Spanish army on the right near the Tagus, the town of Talavera, its front protected by redoubts, ditches, mud walls, and felled trees. In this position they could hardly be seriously attacked. The British infantry on whom the general could depend, occupied the left of the line, which was open in front, but its extreme left rested upon a steep hill, which was the key of the whole position. The whole line extended in length about two miles.

On the 27th of July the French moved from St. Olla, crossed the river Alberche, and drove in the British outposts, and knocked two of their brigades on the head, to back steadily across the plain into their assigned position in the line. Victor now attacked the British left, whilst the 4th corps made a demonstration against the Spaniards on the right, several thousands of whom, after discharging their pieces, fled panic-struck to the rear, followed by their artillery, and creating the greatest confusion among the baggage retainers and mules, &c. and it was with difficulty that Generals Wellesley and Cuesta prevented the rest of the Spanish troops from following the example. Luckily the position of the Spanish army was strong in front, and the French, not knowing exactly what was going on, made no further attack on that side; their efforts were directed against the British left, which they succeeded for a moment in turning, and they gained the summit of the hill; but General Hill, being ordered to that point with more troops, drove the French down after an obstinate struggle which lasted till after dark, and in which the French lost about 1000 men and the British 800. Next morning, the 28th, the French renewed the attack, which was again repulsed after losing about 1500 men. After a pause of some hours the attack was renewed upon the whole British front. Heavy columns of French infantry of Sebastian's corps entered the British right under General Campbell, which joined the Spanish army, and was joined in turn by the British division on the right. The general staff of the enemy, who were near the hill, and expected the British cavalry battle, found it too late to join in the action. The British cavalry, in the mean time a French division on the right of the British army, had got possession of the hill, and the British troops were then ordered to advance, and they speedily overran the enemy's line of battle, and drove them from the field. The British army, after a battle in which more than 12,000 French and 8000 British were killed or wounded, advanced to the hill of Alcaraz. The British victory was complete; the army under Wellington was in possession of all the passes from Spain into Portugal, and the French army was in possession of the passes from Portugal into Spain.
left, and here a cavalry fight occurred in which the 23rd Li.4ht Dragoons lost one-half of their number. General Wellesley had taken the precaution of posting the Spanish division of the right rear of the line, and the right of both armies, and the sight of these effectually precluded any further advance of the French on that side. The principal attack of the French was against the British centre, with which was joined the right wing of the Spanish army. The French columns came quite close up to the British line, but they were received with a discharge of musketry which made them reek back in disorder. The Guards then charged them, and in the course of the moment the enemy were carried too far, upon which the General immediately ordered a general retreat, retreating in good order and dragging back all the French who had advanced, and those who had been repulsed rallied and faced again. While the French batteries poured their shot upon the flank of the Guards, who in their turn drew back in some disorder; at the same time the German Legion, which was on the left of the French, got into confusion, and the British centre was thus broken. This was the critical moment of the battle. General Wellesley, who, from the hill on the left of the position, had a clear view of the whole field, seeing the charge of the Guards, and expecting the issue of it, immediately ordered the 48th regiment, under Colonel Donellan, which was posted on the hill on the left, to advance in support of the centre, and at the same time directed General Cotton's light cavalry to move up to the hill, which, he supposed, would be occupied by the retreating French, and wheeling back by companies let them pass through the inter vals; then, resuming its line, the 48th marched against the right of the pursuing columns, plated them, and this double charge of the French themselves charged upon them with a fire and regularity, checked their forward movement. The Guadarrama and Germans quickly rallied, and the brigade of light cavalry coming up the rear at a trot, the French began to waver, and at last gave way and retired in their original position, their retreat being protected by their light troops and artillery. The British reduced to less than 14,000 men, and exhausted by fatigue, were unable to pursue them; and the Spanish army, which had been accorded engaged, was incapable of making any evolutions; and when the evening was advanced, the British, having this day's battle, thus could not be engaged, nor was it possible that it had occupied in the morning. The French were repulsed at all points, and lost two generals and 480 officers, and about 600 wounded, besides the loss of 17 guns. On the side of the British, two generals and 800 men were killed, and three generals and about 4000 men wounded.

The next morning, July 30th, at daybreak, the French army made a new movement; it was to the Alberche, and this movement was anticipated and followed up by General Robert Craufurd, which the English camp from Lisbon and the 43rd, 52nd, and 95th. This was the light brigades, which at returns acquired a military celebrity for its lightness of its movements.

Sir Arthur Wellesley sent on the 29th and 30th in establishing his hospitals in the town of Talavera, and endeavored to get provisions, as his men were nearly starved. In this he was not at all assisted by the Spanish authorities or the Spanish inhabitants. "We are miserably supplied with provisions—" he wrote to Lord Castlereagh on the 1st of August from Talavera: "the Spanish armies are now so numerous that they eat up the whole country. They have no magazins, nor have we, nor can we collect any, and there is a scramble for everything. I think the battle of the 28th is likely to be of great use to the Spaniards; but I do not think them in a state of discipline to contend with the French." (Dispatches, iv, p. 554.)

King Joseph, with the 4th corps and the reserve, moved on the 1st of August farther back to Illescas, on the road between Madrid and Toledo, in order to oppose the army of Andalusia under Venegas; and Victor, who had remained on the Alberche with the 1st corps, retreated likewise on the road to Madrid, from the 3rd of July to the 4th of August, when the British army reached the town of Cuesta.

Sir Robert Wilson on his flank. Sulf was now advancing from the north with less than three corps, one of which, commanded by Mortier, entered Plasencia on the 31st, having passed, without opposition. The other was the reserve division, the defile of Elnos, which Cuesta had promised to give up to. The 2nd corps, entered Plasencia on the 1st of August, whilst NAY was moving on from Salamanca in the same direction. They found Plasencia deserted by most of the inhabitants, and no intelligence of the position of the British and Spanish armies, except vague rumors of a battle having been fought a few days before. On the 2nd of August Sir Arthur Wellesley learnt that the enemy had entered Plasencia. Supposing a retreat to Plasencia, he thought it possible to secure only 15,000 men, and that his intention was to join Victor, he determined to go on to him before he could effect the junction: he therefore marched on the 3rd of August to Oropesa with the British army, leaving General Blanford, with the Portuguese cavalry, to protect the hospitals; and in case he should be obliged by any advance of Victor to leave Talavera, to collect carts to move away the wounded. The position of the hostile armies was now very singular: they were all crowded along the road between Madrid and Toledo, with the British army on the right, facing the French army, and on the left, facing the Portuguese troops. Porta Josep and Sebastiani were at Illescas and Valdemoro, between Madrid and the Tagus, while the advanced posts of the French were at or opposite the town of Toledo. Victor was lower down on the right bank, at Maqueda, near the Alberche, watching Cuesta, who was at Talavera. General Wellesley was farther down, at Oropesa. Soult was on the Tietar, on the road from Plasencia to Almazara. Beneford, with the Portuguese, was said to be moving farther west along the frontiers of Portugal. "The allies under Wellesley and Cuesta hold the centre, being only one day's march assunder; but their force, when concentrated, was no more than 47,000 men. The French army stood on the Tagus, with which was joined the right wing of the Spanish army, and the right of both armies, and the sight of these effectually precluded any further advance of the French on that side. The principal attack of the French was against the British centre, with which was joined the right wing of the Spanish army. The French columns came quite close up to the British line, but they were received with a discharge of musketry which made them reek back in disorder. The Guards then charged them, and in the course of the moment the enemy were carried too far, upon which the General immediately ordered a general retreat, retreating in good order and dragging back all the French who had advanced, and those who had been repulsed rallied and faced again. While the French batteries poured their shot upon the flank of the Guards, who in their turn drew back in some disorder; at the same time the German Legion, which was on the left of the French, got into confusion, and the British centre was thus broken. This was the critical moment of the battle. General Wellesley, who, from the hill on the left of the position, had a clear view of the whole field, seeing the charge of the Guards, and expecting the issue of it, immediately ordered the 48th regiment, under Colonel Donellan, which was posted on the hill on the left, to advance in support of the centre, and at the same time directed General Cotton's light cavalry to move up to the hill, which, he supposed, would be occupied by the retreating French, and wheeling back by companies let them pass through the intervals; then, resuming its line, the 48th marched against the right of the pursuing columns, plated them, and this double charge of the French themselves charged upon them with a fire and regularity, checked their forward movement. The Guadarrama and Germans quickly rallied, and the brigade of light cavalry coming up the rear at a trot, the French began to waver, and at last gave way and retired in their original position, their retreat being protected by their light troops and artillery. The British reduced to less than 14,000 men, and exhausted by fatigue, were unable to pursue them; and the Spanish army, which had been accorded engaged, was incapable of making any evolutions; and when the evening was advanced, the British, having this day's battle, thus could not be engaged, nor was it possible that it had occupied in the morning. The French were repulsed at all points, and lost two generals and 480 officers, and about 600 wounded, besides the loss of 17 guns. On the side of the British, two generals and 800 men were killed, and three generals and about 4000 men wounded.

The next morning, July 30th, at daybreak, the French army made a new movement; it was to the Alberche, and this movement was anticipated and followed up by General Robert Craufurd, which the English camp from Lisbon and the 43rd, 52nd, and 95th. This was the light brigades, which at returns acquired a military celebrity for its lightness of its movements.

Sir Arthur Wellesley sent on the 29th and 30th in establishing his hospitals in the town of Talavera, and ended availing to get provisions, as his men were nearly starved. In this he was not at all assisted by the Spanish authorities or the Spanish inhabitants. "We are miserably supplied with provisions—" he wrote to Lord Castlereagh on the 1st of August from Talavera: "the Spanish armies are now so numerous that they eat up the whole country. They have no magazins, nor have we, nor can we collect any, and there is a scramble for everything. I think the battle of the 28th is likely to be of great use to the Spaniards; but I do not think them in a state of discipline to contend with the French." (Dispatches, iv, p. 554.)

King Joseph, with the 4th corps and the reserve, moved on the 1st of August farther back to Illescas, on the road between Madrid and Toledo, in order to oppose the army of Andalusia under Venegas; and Victor, who had remained on the Alberche with the 1st corps, retreated likewise on the road to Madrid, from the 3rd of July to the 4th of August, when the British army reached the town of Cuesta.

Sir Robert Wilson on his flank. Sulf was now advancing from the north with less than three corps, one of which, commanded by Mortier, entered Plasencia on the 31st, having passed, without opposition. The other was the reserve division, the defile of Elnos, which Cuesta had promised to give up to. The 2nd corps, entered Plasencia on the 1st of August, whilst NAY was moving on from Salamanca in the same direction. They found Plasencia deserted by most of the inhabitants, and no intelligence of the position of the British and Spanish armies, except vague rumors of a
Sir Arthur Wellesley now moved his head-quarters to Deluytse, and afterwards to Janice, on the high road to Portugal, effecting a strong rear-guard to protect the south bank of the Tagus, and prevent the enemy from passing the river. The bridge of Almaraz had already been broken by the Spaniards. Custa, following the British movement, passed to the south of the Tagus by the bridge of Azunobe, followed by the French, who dispersed his force, and crossed the river on the 8th with a numerous cavalry, overpowered the Spanish rear-guard, and seized the g Tunes. General Wellesley however caused the remainder of the Spanish artillery to be dragged up the mountains of Meta d'Obor, a strong position, and to be placed on the heights of Mirabete, forming the bridge of Almaraz. The line of defence of the Allies was thus re-established. Meanwhile King Joseph recalled Mortier's corps, which had crossed the Tagus at Tamega, and was ordered to join Sebtióan against Venegas, who had in advance advanced to Almodovar, near Toledo. Marshal Ney, on the other side, whom Soult had directed to fort the Tagus below Almaraz, could not dis-cover the ford. Soult now proposed to march with his three corps by Conia and Almabuen, and reach Lisbon, by the right bank of the Tagus, before the English; but Ney, Jouard, and King Joseph opposed the plan, and soon afterwards a despatch came from Nap-oleon, dated after the battle of W.tarn, from the Austrian emperor's palace at Schönbrunn, forbidding further operations against the British, and intimating that the termination of the Austrian war placed at his disposal should reach Spain.

The Emperor Napoleon now, to crush his enemies, trusted chiefly to his overwhelming masses, which, though recruited much from the Spanish cavalry in his armies in Spain was beyond all precedent. Napoleon was resolved to play a sure game. He had already drawn 620,000 men to Spain, and yet he did not think them enough. His numbers were too great, massed on one side, the smallest of which, that will succeed, I thus wrote to King Joseph before the battle of Talavera. It is worthy of remark that Sir Arthur Wellesley, writing about the same time, said, I conceive that the French have never fought a battle of so large a proportion of numbers. Soult's army now went into cantonments in Estremea de Leon, near the borders of Portugal. Sebastiani having defeated Venegas at Almonacid, drove him back upon the Sierra Morena. King Joseph was again residing quietly at Madrid.

In England, on the receipt of the news of the battle of Talavera, Sir Arthur Wellesley was raised to the peerage by the titles of Baron Douro and Viscount Wellington. Some few days afterwards, he left his head-quarters at Badajoz, and placed his army in cantonments on the line of the Guadiana. His chief motive was the neglect of the Spanish armies in supplying his army with provisions, which obliged him to draw near his magistrates in Portugal, where, in consequence of his repute, he was kept in constant op-rating with the disinterested Spanish armies. Lord Wellington had contrived, notwithstanding Custa's neglect, to carry away 20,000 sick and wounded from Talavera; the remaining 16,000, whom he was obliged to leave there, recommended earnestly to the French generals, Mortier and Kellerman, and his expectations were not deceived. Marshal Mortier in particular showed the utmost kindness to the British wounded, and would have attended to before his own men.

In October Lord Wellington repaired to Lisbon, and proceeded to reconnoitring the whole country in front of that capital, for it was then that he resolved upon the construction of the celebrated lines of Torres Vedras, which enabled him to battle all the efforts of the French in the following year. We can only refer the reader to the 'Memorandum' he wrote at Lisbon on the 20th of October for Lieutenant-Colonel Fletcher, of the Engineers, in which he clearly points out the double line of position, the inevitable and redoubtable, the number of men required at each post, &c., as if the whole were already in existence before his eyes. This paper, so remarkable considering the epoch and circumstances in which it was written, is a most striking evidence of Wellington’s foresight. In the following year, the capture of Badajoz, owing to the great number of troops of the French, the barbarous conduct of the British authorities, the numbers of men required for each post, &c., the conclusion is a striking one. The plan of his course had never been said or even whispered at the time. He returned to his head-quarters at Badajoz, whence he made an expedition to Seville, where he conferred with his brother the Marquis Wellesley, who was then the British ambassador in Spain, and whom he accompanied to Cadiz. On the 11th of November he returned to his head-quarters at Badajoz. At the same time another fatal blow was committed by the enemy. On the 25th of November, Supre- me Junta ordered the army of Andalusia, joined by the French army of Estremadura, to advance suddenly upon Madrid, and this without any previous communication with the viceroy. Dugout Wellington, who was at Badajoz, or, with the Duke of Parque and the army of Estremadura, was in communication continually with his chief. Venegas, the general of the army of Andalusia, had been the favorite of the Junta, and the officer who was in his favor. It is now retired, and made to command the army of Estremadura. These two armies, each composed of the principal regular forces of the Spanish, and which, posted within the line of the Tagus and along the range of the Sierra Morena, protected, and might long have protected, the south of Spain, were drawn away upon a foolish attempt. Arriea, with nearly 50,000 men and 60 pieces of artillery, advanced into the plains of Mancha, and was attacked on the 18th of November, in the open fields of Ocaña, by the two French corps of Mortier and Sebastian; and, although his men fought with sufficient courage, yet he was completely routed, with the loss of more than one half of his army, and all his baggage and artillery, with the exception of 15 guns. About the same time the Duke of Parque, with a part of his army, was repelled from the city of Salamanca by the French army. Wellington had directed his army to be reviewed on the Tagus, or, as the French called it, the wall which had previously been so completely lost by the ignorance, precaution, and mismanagement of those whose direction it was in charge of. I have mentioned, however, that they were to preserve their arms, or even one of them, the empire. The French could have sent no reinforcements which could have been of any use; time would have been gained; the state of affairs would have improved daily; all the advantages in the field could have been turned to account by any diversion on the continent, or by the growing discontent of the French themselves with the war, the French army must have been driven out of Spain. But nothing will answer except to fight great battles in plains, in which the defeat of the Spanish army is certain as the commencement of the battle. They will not credit the accounts I have repeatedly given them of the superior numbers of the French; they will seek them out, and find them in strength.

Lord Wellington now directed towards the north-east, for he foresaw that the storm would burst upon Portugal from that quarter. He accordingly retired from Spanish ground altogether into Portugal, and moving through Alentejo with the mass of his army in December, crossed the Tagus at Abrantes; and thence marching to the Mondego, fixed his head-quarters at Vise in January 1810, having his outpost along the frontiers of Spain towards Ciudad Rodrigo. He left General Hill’s division south of the Tagus to protect Alentejo. In the mean time, Spain and Beesford were indefatigable in their endeavours to raise the Portuguese regular army to a state of efficiency in numbers, armament, and discipline.

Campaign of 1810.—By his campaigns of 1809 General Wellington had delivered Portugal from the French. In the campaign of the early part of 1809 he had again repelled a fresh invasion of the northern part of that kingdom. The subsequent Spanish campaign of the same year, which was undertaken with a view of striking the French army away from Castile and recovering Madrid, failed through want of good management on the part of the Spanish generals, and of discipline in the Spanish armies. The battle of Talavera, the first fought by Wellington on Spanish soil, was so confused, and produced such a result, and the British general was obliged to evacuate Spain. Fresh blunders on the part of the Spaniards led to the con- qiiest of Andalusia by the French. The war in Spain then assumed the character of a partisan warfare, and Wellington saw that it would be in vain for the present to expect that
Spain could make any adequate effort to shake off the French yoke. Portugal, however, was free, and Wellington thought that she might be preserved by means of a British force of 80,000 men, assisted by an effective Portuguese army. As in addition to the militia, even supposing the French should obtain possession of the remainder of the Peninsula. This he stated, in a letter to Lord Castlereagh, written from Mudela, 25th of August, 1809, soon after his retreat from Talavera. His determination being founded upon facts, of the utter inability of the Spanish armies, as they were then constituted, to keep the field against the French. The following passage, which concludes his account of the military affairs, does not leave me, who really believe that much of this deficiency of numbers, composition, and discipline, is to be attributed to the existing government of Spain. They have attempted to govern the kingdom, in a state of revolution, by an adherence to old rules and systems, and with the aid of what is called enthusiasm; and this last is, in fact, no aid to accomplish any thing, and is only an excuse for the irregularity with which everything is done, and for the want of discipline and subordination of the armies. People are very apt to believe that enthusiasm carried the French through their revolution, and was the parent of those exertions which have nearly conquered the world; but if the subject is nicelv examined, it will be found that enthusiasm was the same only, but that for a short period which has been passed with those r e s o u r c e s under the system of terror, which first stopped the Allies; and that a perseverance in the same system of applying every individual and every description of property to the service of the army, by force, has since conquered Europe. The French army, in Spain, as they did everywhere else, was that of taking possession by force or everything they wanted. They ordered rations at every town, and they arrested, shot, or hanged all who put any obstacle in their way. The English generals, the allies of Spain, could not be spared adverse advice. O'Donnell was assisted by the nature of the ground, which was interspersed with numerous fortresses, and also by the British squadron along the coast, and by the organisation and faculty for rapid operations which the British army is capable of. The Spanish provincial was too remote to have any influence on the operations in Portugal and Andalucia. The conquest of Portugal was the great object of the French campaign of 1810.

About the middle of May Marshal Massena, Prince of Essling, arrived at Valladolid, having been sent by Napoleon to take the command of the army assembled in Old Castile and Leon, which assumed the name of the Army of Portugal. He had also military command over the provinces of northern Spain. His force consisted of the corps of Junot, the reserve cavalry under Monbrun—is of 72,000 men under arms for the field, besides garrisons, detachments, &c., in the provinces of Valladolid, Burgos, Segovia, and Palencia. This army, which was detached from the course of the campaign, the 9th corps, under Dross, consisting of about 18,000 men, Lord Wellington had to oppose the whole of this force with about 54,000 British and Portuguese regular troops. There was moreover a considerable Portuguese militia, employed mostly in the peninsula, and in the provinces beyond the Duero, in Lepe and Algarve—in short, on the wings of the regular force, it must be observed also that Massena could concentrate his whole force for his attacks on Portugal and Tagus, whilst Lord Wellington was obliged to leave part of his force south of that river, to guard against any sudden movement from the French army of Andalucia, which was less than 80,000 strong, of which a part might attempt to march into Alentejo. Again, Massena's troops were mostly old soldiers, flushed with success and in a high state of discipline, whilst Lord Wellington could only constantly rely upon British part of his force, about 25,000 men, as the Portuguese regular army was yet nurtured, and the men were dear to them. Wellington has been described in the eyes of the field. Marshal Beresford however had taken great pains with the Portuguese regulars, many of the officers were English, and Lord Wellington had bridged several of the rivers which it was necessary to cross during the operations. Early in June the French invested Ciudad Rodrigo in sight of the British advanced division, which was posted on the Arua. On the 25th they opened their batteries, and the Spanish governor, a brave old officer, defended them till the 10th of July, when, a practicable breach being made
the French entered the place by capitulation. Wellington could not risk his army for the relief of Ciudad Rodrigo: its object was to defend Portugal, and, above all, Lisbon. He states in the clearest manner his reasons for not attempting to relieve Ciudad Rodrigo in his despatch to Lord Hill in the morning of the 15th. He was advised in answer to the charges in the French 'Moniteur.' He retained his position on the left bank of the Coa, and the French advanced to that river, and in so doing the corps of Massena, under Generals Soult and Moncey, encountered the British light division of Massier, General Trumulo, who, being in possession of a much superior force, and lastly effected his retreat by a bridge across the Coa, which the French unsuccessfully attempted to pass. The fire of the British killed and wounded about 1000 of these French, and left the river, and was useless, though it gave Massena a specimen of the resistance that he had to encounter in his march to Lisbon, which was the declared object of his expedition. On entering the frontiers of Portugal, after taking Ciudad Rodrigo, Massena issued a proclamation to the Portuguese in the usual style of French proclamations of those times, abusing the English as the cause of all mischief, and attributing the crimes of an English army in Portugal to the "insatiable ambition" of England. He entered at the English for not allowing the French, with whom they knew they could not have done in the face of an enemy three times as strong. Massena ended by recommending to the Portuguese population to remain quiet, and receive the French with hospitality as well as another nation, and for their persons and property. How this last promise was kept from the beginning is stated by Lord Wellington in a counter-proclamation which he issued a few weeks afterwards, dated Celorico, August 4th:—"The time which has elapsed since the access of the French to the left and the right of the English position; one French column reached the top of the ridge, and was in the act of d-playing when it was repulsed by General Picton's division, as far as the next village, which they attempted to take and on the left the French were likewise repulsed and thrown down the hill by a charge from the bayonet of Craufurd's division and a Portuguese brigade. The French lost one general and about 1000 killed, two generals and about 5000 wounded and 3000 prisoners. The loss of the Allies did not exceed 1300. This movement," says Wellington, "has brought the Portuguese levies into action with the enemy for the first time in an advantageous situation, and they have proved that the troops of Portugal are for the time being thrown away, and that they are worthy of contending in the same ranks with British troops in this interesting case, which they afford the best hopes of saving." ('Dispatches,' vol. iv., p. 470.)

One of the moves of Lord Wellington in fighting the battle of Busaco was to give time to the population of the country in his rear to remove out of the way of the enemy with their goods and provisions, especially from Coimbra, a populous and wealthy town, but the orders given to effect it were ill obeyed. Massena did not attempt again to force the position of Busaco, but moved off his army by the pass of Balseval, in the mountains north of Busaco. Lord Wellington had directed Colonel Trant to occupy this pass as soon as the French army had crossed the river, but, and arrived too late and with too small a force to arrest the march of the French, who descended into the maritime plains, and seized on the road leading from Oporto to Coimbra in the rear of the British.

On the 5th of September the Allies quitted the position of Busaco, and, crossing the Mondego, began their retreat towards Lisbon. On the 1st of October the British rear-guard, after some skirmishing with the French, evacuated Coimbra, accompanied by all the remaining inhabitants, who were away with whatever they could carry, and the sick, the aged, and the children, on carts, mules, and donkeys, not knowing whether they were going, and encumbering the road, whilst the French cavalry was hovering on the flanks and pins, not in a position to protect those who saw it can never forget. The French entered the forsaken city, where they found ample stores of provisions. On the 2nd of October Lord Wellington's head-quarters were moved to Leiria, where he stayed two days, the French marched away, as if they were giving up the retreat with great ease and regularity. General Hill with his division moved by Thomar and Santarem, the centre of the army by Leiria and Rio Mayor, and the left by Alcanena and Odivelas. Massena followed in one column by the centre or Rio Mayor road; but the French had gained a position of place between his advanced guard and the light division which formed the British rear. On the 8th the allied army entered the lines which had been prepared for them, just as the autumnal rains, which fell heavily in Portugal, were beginning to set in. Never was a retreat, before a formidable enemy, effected with more ease or so little loss.
On the 10th of October the whole army was within the lines.

The line of defence was double. The first, which was 29 miles long, began at Alhendra on the Tagus, crossed the valley of Arna, which was rather a weak point, and passed along the skirts of Mount Agraço, where the town, a large and strong re-look: it then passed across the valley of Zibeira and skirted the ravine of Rana to the heights of Te-Me Vedres, which were well fortified; thence the line followed the course of the little river Zindara to its mouth on the banks of the large river Zibreira. The second line was fixed corresponding with every part of the position.

The second line, at a distance varying from six to ten miles in the rear of the first, extended from Quintellas on the Tagus, by Bucelles, Monte Chique, and Mafra, to the mouth of the little river S. Lourenço on the sea-coast, and was 94 miles long. This was the stronger line of the two both by nature and art, and, if the first line were forced by the enemy, the retreat of the army upon the second was secure at all times. Both lines were secured by breastworks, abatis, strong redoubts and earthworks, and defended with a salient line in the rear. There was a line to secure the embarkation of the troops, should that measure become necessary, enclosing an en-trenched camp and the Port of S. Julian. More than 100 redoubts and 600 lines of bivouacs were scattered along these lines. Lord Wellington had received reinforcements from England and Cadiz; the Portuguese army had also been strengthened, and the Spanish division of La Romana, 5000 strong, came from Estremadura to join the army. The Portuguese artillery, which had been the last, was rapidly repaired and mounted. It was manned by engineers and armed with the most modern gun-boats flying the right of the British line. Altogether these lines of defence were of stupendous strength, conceived by the military genius of Lord Wellington, and executed by the military skill of the British engineers.

Massena seems to have been taken by surprise at the sight of the lines, and he employed several days in reconnoitering them. He made some demonstrations in order to make the British divisions show out their force; but after one or two slight attacks, which were repulsed, he made no further attempt. He put the second and eighth corps partly in the villages and partly in bivouac in front of the right and centre of the British position, leaving the sixth corps at Olta in his rear. The siege batteries, which had been left behind and commenced forming magazines at Santarem, for this purpose sent moveable columns to scour the country for provisions, for he had entered Portugal without magazines, and had only six days' supplies, which many however threw away or wasted on the road. The country had been partly stripped by the inhabitants, who had retired to the mountains or within the lines, and the French foraging parties destroyed what was left, so that for many leagues in rear of the French the country became a scene of devastation and almost a desert. In addition to this, the Portuguese militia under Trant, Millar, and Wilson, came down from the north and cut off all communication between Massena's army and the lines of the Spanish frontier. Whilst the French were in march for Leiria, the British troops began to arrive at Oporto, Coimbra, seized many prisoners, and all the sick and wounded, between four and five thousand in number, whom he removed to Oporto. Trant and Wilson came down towards Ourem, Thomar, and the banks of the Zêzere, having in the rear of Massena, who was obliged to retreat back a whole division to hold them in check. Towards the end of October, Massena sent 2000 men across the Zêzere, but these were easily disposed of with a strong escort by way of Pesuaco to Ciudad Rodrigo, whence he hastened to Paris to inform Napoleon of the real state of affairs in Portugal.

There was now no idea of attempting the force the British lines unless he received large reinforcements. He had entered Portugal with about 70,000 men, of whom 15,000 had been either killed or taken prisoners or were in the hospitals; his army had become very sickly in consequence of privations and of being exposed to inclement weather mostly without shelter, and bivouacking in low grounds. On the 10th of November he began a retrograde movement, with great order and caution, for the purpose of giving his army a respite from the winter. On the 14th the French second corps was established at and near Santarem, in a very strong position; the eighth corps at Pernes; and the sixth corps at Thomar, farther in the rear. Massena's head-quarters were fixed at Tomar, and his general division was placed on the left bank of the Tagus, opposite Santarem. Wellington's head-quarters were fixed at Cartaxo. Both armies were now in cantonments for the winter. The ended the campaign of 1810. As a defensive campaign on the part of Lord Wellington it was successful, for the French army at the end of that year held no other ground in Portugal than that on which its divisions stood, being hemmed in between the northern bank of the Tagus, the Rio Mayor, and the ridge of the Serra de Estrela, having the allied army in front of it. These lines were already strengthened on its rear, and its communications with Spain intercepted

All the north of Portugal was free from the French, and also the whole of the kingdom south of the Tagus, and the whole of the country west of the Serra de Estrela, the people of that part of Portugal rejoicing to have rid themselves not only of the French, but of their Mozarabic faction, and carried off the provisions; but the population east of the mountains, and between them, the Tagus, and the Zêzere, had remained in fancied security; so that, when Massena withdrew his army to that quarter, he found the towns of Thomar, Oporto, Coimbra, Abrantes, in possession of the Allies, as well as all the fortresses, with the exception of Almeida. As the French had advanced by the valley of the Mundeio and the country west of the Serra de Estrela, the people of Portugal had done all in their power to support him and helped him in every way. All our military arrangements are useless if they can find subsistence on the ground which they occupy. Then the boats are left at Santarem in order to give the enemy an opportunity of acting upon our faults. It is not easy to break to the populace the advantages which we have obtained, and that I should advise the King's Government to withdraw the assistance which his Majesty affords them, if they interpose in any manner with the appointments of Marshal Beresford, who has been assigned to the command of the divisions of the army; or with any of the points which, under the original arrangement with Marshal Beresford, were referred exclusively to his management. I propose also to report to his Majesty's Government, and refer to their consideration the duty which is at present incumbent on the Government to refuse or delay to adopt the civil and political arrangements recommended by me, and corresponding with
the military operations which I am carrying on. But it appears that the Portuguese Government have lately discovered that we are all wrong; they have become impatient for the defeat of the enemy, and, in imitation of the Central Junta of Spain, call out for a battle and early success.

In another letter, dated Rio Mayor, October 6, addressed likewise to Mr. Stuart, the junta of Portugal spoke to me of the field that, luckily, I hurried about and that shall be seen. You will do me the favour to inform the Regency, and above all the Principal Souza, that, his Majesty and the Prince Regent having intrusted me with the command of their armies, and having assured me of their support, if I do not suffer them, or anybody else, to interfere in them; that I know best where to station my troops and when to make a stand against the enemy; and I shall not alter a system formed upon mature consideration upon any suggestion of their Highnesses, but will preserve the tranquillity, I recommend them to look to the measures for which they are responsible, and which I long ago recommended to them, viz. to provide for the tranquillity of Lisbon, and for the food of their own army and of the people, while the troops are to be engaged in the enemy. Campanarios of 1811. During the months of January and February the armies in Portugal remained in the same respective positions. The low lands being flooded rendered field operations impossible. Meanwhile the 9th corps under Drouet had entered Portugal by the valley of the Mondego, and was reinforced by some additional troops. Thus reinforced Massena’s army, by being posted on its right about Leiria. At the same time Soult, who commanded the army of Andalucia, received orders from Napoleon to act in concert with Massena, by attacking Portugal south of the Tagus; and was reinforced by the divisions of Soult, consisting of about 70,000 men, and placed under Marshal Bessières, duke of Istria, who ordered to support and furnish all necessary assistance to the army of Portugal.

Letter from Berthier, Prince of Essling, to the Prince of Essling (Massena), Paris, January 16, 1811; and another from the Duke of Dalmatia (Soult), January 24, 1811; and another from the same to the Prince of Essling, February 7, 1811; in Appendix to Napier, vol. iii. "Make a bridge on the Coa and link up with Soult. Let the Soult form a junction. Meanwhile keep the English in check, and make them lose men every day by engagements of the advanced guards. Their army is small, and they cannot afford to lose many men. Besides, people in London are aware of the idea of crossing the Mondego and invading Portugal, and they must be convinced. Mountbrun had a detachment of the bridge, and placed guards at the ford, but they determined to defend the town, thinking that, if he could carry a sudden assault, Massena could not stay long on the left bank of the Mondego with the allied army at his heels. On the 11th of March Mountbrun, reinforced by the Portuguese militia, took the town by storm, and on the 12th made an attempt to force the bridge, but his men were repulsed by grape-shot. Mountbrun fancied that Trant had been reinforced with some English regiments by sea, and having made his report, Massena relinquished the idea of crossing the Mondego, and sent a division by Ponte de Mincelves and the left bank of the Mondego. Thus Coimbra was saved from the impending visitation. Massena resumed his retreat on the 13th of March in rather a hurried manner, being on the point of having his left flank turned by the Portuguese army. When in the path over the mountains of Anciso, Ney, in command of the rear-guard, set fire to the town of Condeixa, in order to stop the British artillery, but the light division pursued the retreating enemy, and penetrated between their columns, till night was coming to an end, and then began to press the French very hard. By the morning of the 14th, when the fog which enveloped the mountains began to clear off, Ney was seen posted on a hill near Casal Nova. The light division attacked him; and Picton’s and Cole’s
On this rear-guard the French retired with admirable precision from ridge to ridge, covering his rear with guns and light troops, until he gained the strong defiles of Miranda de Coimbra and the banks of the river, and leaving Ney to cover the passage of the river, without however risking an action. Ney remained on the left bank, and took up a position near the village of Fons de Arronc. The Allies, coming up about noon, encamped in a wood in which they were intercepted by the means of carrying provisions along with the army. Nothing could be got from the country, which had been twice ravaged. Some of the Portuguese brigades were actually starving; many men fell off and died, and to save the rest of the army from the same hardships British commissary-general's means were thus overlaid, and the whole army suffered in consequence. (Dispatches to Charles Stuart, dated Louzio, March 16, and Pombeiro, March 18, and another to the Earl of Liverpool of March 16.)

On the 17th the French armament at the pont of a trestle bridge, the French having withdrawn in the night.

Massena had taken up a strong position on the river Alva, another affiliate of the Mondego, which was swollen by the rains, and had destroyed the bridge of Marcella, apparently intending to remain there some days. He had also sent detachments to scour the neighboring country for provisions. But Wellington marched three divisions by the mountains of Quiteria to Arganil, on the Upper Alva, which movement obliged the French to retreat. At Condeixa, the French intended to throw a barrier along the river, but Wellington had already passed by the pont of a trestle bridge, the French having withdrawn in the night.

In the mountain valleys of the Serra de Estrela, the work of destruction had been carried on by the French during the winter of 1810. The British were searching for provisions in those sequestered valleys, and when they fell upon a hamlet or farm-house they showed no mercy to the inmates. Sometimes in the mountains they encountered several families huddled together in a cave, with their women and children, and when the weather was bad, they were soon dislodged—the females pared for a time, but not in mercy. It happened however that times these marauding parties were small, and they were overpowered by the peasantry, who gave no quarter.

Lord Wellington having placed his army in cantonments between the Coa and the Agueda, and made arrangements for the blockade of Almeida, set out for the south to see the state of his troops, and, at the same time, detach a force to the south, and, with the aid of the allies, laid the troops in Almejto, in the absence of General Hill, who had gone home on leave. The Spanish General Menjízabal, having been utterly defeated by the French in the preceding February, Scott had invested the place in such a manner that it was only 8000, voted by the British Parliament, and by subscriptions raised in England. After the retreat of Massena they returned to their homes, when the poorer classes received articles of clothing during the remainder of that year and the following winter.

up Viana d'Avé and his communication with Sbangal, and ordered the 7th and 8th divisions to retire across the plain, and take up a new line on a ridge which runs from the Du Casa and Toreno, nearest at right angles with the original position. The village of Fuentes de Oñoro thus became the left of the new position, and the right of the French, beyond the Toreno, and between that and the Guadarrama. This movement was well executed, though under very critical circumstances, for the British squares had to cross a vast plain, exposed to the charge of a numerous French cavalry supported by small but well-ordered British infantry, and too weak in numbers to offer any real protection. The non-combatants, who had gathered behind the British line, were hurrying away, driven by the French horsemen across the plain. Colonel Napier says that "in all this war there was not a more dangerous hour than this, and the whole position of the British, the Toreno, was covered with a confused multitude, amidst which the squares appeared but as specks; for there was a great concourse, composed of commissariat followers of the camp, servants, baggage, led horses, and peasants attracted by curiosity, and finally, a great number of men coming out of the woods. The 7th division was separated from the army by the Toreno; 5000 French cavalry, with fifteen pieces of artillery, were close at hand impatient to charge; the infantry of the 6th corps was in order behind the same, and the wood was covered by the skirmishers of the 6th corps; and if the latter body, pivoting upon Fuentes, had issued forth, while Drouet's divisions fell on that village, while the 6th corps attacks the light division, and while the whole of the cavalry made a general charge, the British squares would have been driven violently in upon the 1st division, in such a manner as to have intercepted the latter's fire, and broken their ranks. No such effect however was made; Montbrun's cavalry, moving bow down but finally, squares, the plain was cleared, the cavalry took post behind the centre, and the light division formed a reserve to the right of the 1st division, sending the riflemen among the rocks to connect it with the 7th division, which had arrived at Fuentes, and was to both sides of the village. Sanche's cavalry, however, formed a new front, so finely lined with troops, the French stopped short, and commenced a heavy cannonade, which did great execution, from the closeness of the allied masses; but twelve British guns replied with vigour, and the violence of the enemy's fire abated; their cavalry then drew out of range, and a body of French infantry attempting to glide down the ravine of the Toreno, was repulsed by the riflemen and light companies of the Guards. But all this time a force battle was going on at Fuentes de Oñoro. Massena had turned his head to the right, and the British were this moment attacked by the 10th division. When Montbrun's cavalry should turn the right wing. It was, however, two hours later ere the attack commenced. The three British regiments (24th, 71st, and 79th) made a desperate resistance; but finally, having been broken, they retired to the desultory fighting of light troops, they were pierced and divided: two companies of the 79th were taken, Colonel Cameron was mortally wounded, and the lower part of the town was carried: the upper however was still held, and the rolling of the musketry was incessant. Had the attack been made earlier, and the whole of Drouet's division thrown boldly into the fight, while the 6th corps, moving through the wood, closely turned the village, the passage must have been forced, and the left of the new position outflanked; but now Lord Wellington, having all his reserves in hand, detached considerable masses to the support of the regiments in Fuentes. The French continued also to reinforce their troops, until the whole of the 6th corps and a part of Drouet's division were engaged, when several British regiments, particularly the 36th and 22nd, which were on the banks of the stream, and amongst the lower houses; another upon the lower heights and round the church, and some of the enemy's skirmishers even penetrated completely through to the main body; but before the village was carried, it was relieved by its defenders; and in a charge of the 71st, 79th, and 88th regiments, led by Colonel Mc'Kinnon, against a heavy mass which had gained the chapel eminence, a great number of French fell. In this manner the fight lasted until evening, when the lower part of the town was abandoned by both parties—the British maintaining the chapel and crape, and the French retiring a cannon-shot from the stream. ('History of the Peninsular War', iii. 514-16.)

The total loss of the British was 226 killed, 1234 wounded and 317 missing or taken prisoners. The loss of the French was also very great; nearly 6000 dead bodies found in the village. No fighting of any consequence occurred on the left of the British position, where the fifth and sixth divisions were posted to protect the blockade of Almeida, the second corps of the French merely waiting the issue of the battle at Fuentes de Oñoro, and watching for an opportunity of throwing provisions into Almeida, which however did not occur. The battle of Fuentes de Oñoro was of the utmost importance, being a regular pitched battle fought by the French, who were certainly greater, judging from the vast number of the British, and from the strength and size of the French army, against three French corps of infantry and 5000 cavalry. Massena fought the battle for the purpose of relieving Almeida, but he failed, and Almeida a few days afterwards was evacuated by the French garrison in the British. With this battle General Beresford closed his long and arduous career. He withdrew his army beyond the Aeguida, and soon afterwards Marshal Marmont, duke of Ragusa, arrived at Salamanca to supersede him. The order of Napoleon by which Massena was directed to give up the command to his brother-in-law, was to be performed as soon as the latter was allowed to take with him to France his son and one of his aides-de-camp only. Marmont was told to take the reins of command with a firm hand. ('Napier, 'Peninsular War, vol. viii., Appendix viii., p. 629.')

While the battle was happening in the north, Marshal Beresford had invested Badajoz, when Soult marched from Seville to relieve that place. On the 13th of May, Beresford raised the siege, removed his artillery, platforms, and stores, and prepared to march towards the Mondego. He advanced on the ridge of Alberca with above 7000 British infantry, four Portuguese brigades, and Blake's Spanish corps, in all about 30,000 infantry and about 2000 cavalry, but hardly one-half of this force could be depended upon in the field. He had with him the 8th division, and the 9th and 7th divisions were to follow. The French however had with them about 12,000 men. Soult came up with about 19,000 chosen infantry, about 4000 cavalry, and fifty guns. He immediately reconnaited Beresford's position, and determined upon an attack on the right flank of the Allies, which was their weak point, though Beresford had directed his chief attention to the centre, where he had placed his British troops. It was on the French part the same game as at the battles of Talavera and Fuentes; but Wellington was not there, nor were British troops at hand all along the line; and when Beresford, perceiving the immense superiority of the French, was about to face the French marching upon his right, Blake refused, saying that the real attack was against the centre by the bridge of Alberca. There was indeed an attack by the French on the right, but it was only intended to mask and support the grand attack on the left. It was only when the French actually appeared on the table-land on the right, commanding and enfilading the whole position of the Allies, that Blake consented, with much slowness, to change his front. In the mean time the French columns were already in possession of the table-land; their guns opened, and their cavalry outflanking the front, put the Spaniards in disorder, and they gave way. The brigades of the second division, British, were ordered to advance to the right; the first, and Coleman's brigade, while in the act of deploying, was attacked in flank and rear, and nearly destroyed by the French and Polish cavalry; the next, Hongton's brigade, reached the summit, and maintained a desperate struggle. But the men fell fast, ammunition failed, and General Beresford ordered the retreat. The retreat was an ruinous, when, at the suggestion of Colonel Hardinge, General Cole, with the 4th division, was ordered to march up the hill. It consisted of only two brigades, one Portuguese and one British (7th and 23rd regiments), commanded by Sir William M'Intyre; orders to General Beresford to restore the fight and save the army. General Cole directed the Portuguese brigade under General Harvey to move round the hill on the right, whilst Abercrombie's brigade, the last remaining part of the British, advanced to the west of the hill, which was crowned by the French masses and artillery. Six British guns were already in the enemy's possession, the whole French reserve was coming forward to reinforce their
front column, and what remained of Hougton's brigade could no longer maintain its position. The ground was heaped with dead bodies, and the Polish lancers were riding furiously about the captured artillery on the upper part of the hill. General Cole at the head of the flankers, flanked by a battalion of the Lunatic Legion under Colonel Hawk- 

haw, dispersed the lancers, captured the guns, and appeared on the right of Hougton's brigade exactly as Abercrombie's issued out on the left. We must now once more borrow Sir William Napier's eloquent pen:—

"Such a gallant line, issuing from the midst of the smoke, and rapidly spreading, completely disordered and startled the enemy's heavy masses, which were increasing and pressing onwards as to an assured victory: they vanished, hesitated, and then, vomiting forth a storm of fire, hastily endeavored to enlarge their front, as was really done by this overwhelming force, which was signalled through the British ranks.

Sir William Myer's was killed, Cole, and the three colonels, Ellis, Blakeney, and Hawkhaw, fell wounded, and the fusilier battalions, struck by the iron tempest, receded. But the French, in one rush, and with the sudden burst of undisciplined valour, no nervous enthusiasm, weakened the stability of their order; their flashing eyes were bent on the dark columns in their front; their measured tread shook the ground; their dreadful volleys swept away the haf of every-formed line, and marched and recovered, they closed on their terrible enemies, and then was seen what a strength and majesty the British soldier fights.

In vain did Scott, by voice and gesture, animate his Frenchmen; in vain did the hardest veterans, extiricating themselves from the dug-well of the trees, urge the gain time for the mass to open out on such a fair field; in vain did the mass itself bear up, and, fiercely raising, fire indiscriminately upon friends and foes, while the horsemen, dancing on the flank, threatened to charge the advancing lines. But the French continued to resist the attacks, and, as the enemy advanced, endeavor to sustain the attack; their efforts only increased the irresistible confusion, and the mighty mass, giving way like a loosened cliff, went headlong down the ascent. The rain flowed as thick as raindrops, showered with blood, and among the wounded men, the remnant of 6000 incomparable British soldiers, stood triumphant on the fatal hill." (Napier, "Peninsular War," III., 640-1.)

The day was now won, and Beresford ordering the Portu-guese infantry to take post on the right, and the French retreated confusion across the small river on which stands the village of Albuera. About three o'clock the fire had ceased. The allied army had lost in killed and wounded about 7000 men, of whom two-thirds were British. The French lost about 8000 men, including prisoners and killed. On the 16th of May the two armies remained in their respective positions, and Beresford waited in anxiety for another attack, when he had hardly British soldiers enough for his piquets and to take care of the crowd of wounded. On the 17th however he was reinforced by an English brigade, and the following day Soult retired towards Seville, leaving 500 soldiers severely wounded to the generosity of the English.

On the 19th Wellington arrived from the north, followed by two fresh divisions, and gave directions to resume the siege of Badajoz. On the 5th of June, a breach being made in Fort St. Christoval, the assault was given, but failed. On the 9th another attempt at storming was made, which proved equally fruitless. On the 17th, however, with but so little assistance, the town was taken, and the Portuguese and the Salsamaca. Lord Wellington likewise, leaving General Hill with one British division and the Portuguese in Alem-tejo, and giving up the siege of Badajoz for the present, crossed the Tagus with the remainder of his army, and fixed his head-quarters at Fuente Gualinde, on the line of the Agueda. He was looking towards recovering possession of the important fortress of Ciudad Rodrigo, which his advanced parties surrounded and kept in a state of blockade. Towards the end of September, Marmont, having received large reinforce-ments from France, moved upon the Agueda, and by his superiority of numbers and especially of cavalry, obliged Lord Wellington, after a partial engagement at El Bodon, to withdraw his army, which he did in excellent order to his old position on the Cos, where Marmont did not choose to follow him. Nothing more happened after this on that side for the remainder of the year.
was surprised and carried; and on the 14th the convent of San Francisco, likewise situated outside the walls, was carried by assault. The second parallel was then completed, and fresh batteries being established, two practicable breaches were made on the 18th, and orders were given to storm the place. No time was to be lost, as Mar- mount was known to be advancing to relieve the garrison. A part of the light division under General Craufurd, on one side, and General Mackinnon’s brigade, supported by the 94th, D’Avenel’s, and the light infantry, on the other side, were directed for the breaches, whilst Colonel Pack’s brigade attacked the gate of St. Jago, and in less than half an hour from the time the attack commenced the Allies were in possession of the ramparts, and the garrison then surrendered. (‘Dispatches, i. p. 238.) The loss of the Allies was about 2,000 killed and wounded, and of the British about 1,000 killed and wounded. The loss of the garrison was estimated at about 1,000 killed, besides 1,700 prisoners. A large battering-train and a vast quantity of ammunition and stores were found in the place.

Marshal Marmont heard at Valladolid, on the 18th of January, of Wellington’s advance to Ciudad Rodrigo. He quickly recalled Bonet’s division from Asturias, collected his other divisions, and marched, as he thought, to relieve the place; but on arriving at Salamanca he heard of its fall. His astonishment was thus expressed in a letter to Bertrand: ‘My generalissimo! The English have opened fire at a great distance; on the 19th the place was stormed, and fell into the power of the enemy. There is something so incomprehensible in this that I allow myself no remarks, as I am not yet furnished with the necessary information.’

The English garrison, under General Hill, gave a vote of thanks to Lord Wellington, and conferred on him the title of Duke of Ciudad Rodrigo. In England he was raised to the dignity of Earl of Wellington of the United Kingdom, and parliament, besides a vote of thanks to him and his brave army, annexed to the title an annuity of £5000.

Having repaired in some degree the works of Ciudad Rodrigo, Lord Wellington placed it under the command of a Spanish governor, and prepared to move to the south, for he had before resolved to take Badajoz, and take Bonet to Cadiz. Marmont and Soult could unite for his defence. The artillery for the siege was embarked at Lisbon for a fictitious destination, then transhipped at sea into small craft, in which it was sent to Formos, and thence by land across Alemtejo to the banks of the Guadiana. On the 6th of March, leaving one division on the Aguera, Lord Wellington marched the remainder of his army to the south. On the 16th the army crossed the Guadiana, and Badajos was immediately invested, the cast, while several divisions advanced to Alerena and Merida to cover the siege. On the 20th, the Picurins, an advanced post, separated from the body of the place by the small river Rivillas, was taken by storm, and on the 28th two breaches batteries opened their fire on the town. In the meanwhile Soult was collecting his disposable force at Seville for the relief of the place, and Marmont, in order to effect a diversion, entered Portugal by Sabugui and Penamacor, and ravaged the country east of the Serra de Estrella. Lord Wellington accelerated the operations of the siege. On the 6th of April, three breaches having become practicable, orders were given for the assault in the evening. The various divisions passed the glacis under a tremendous fire from the garrison, which greatly thinned their ranks; and they descended into the ditch, and ascended the ramparts, where they were harried by musketry. The Spanish, like harrows, and chevaux-de-frise formed of sword-blades, effectually stopped the way, and the ramparts and neighbouring buildings were occupied by light infantry, who showed their volleys upon the assailants.-lasting hand, disposable force at Seville for the relief of the place, and Marmont, in order to effect a diversion, entered Portugal by Sabugui and Penamacor, and ravaged the country east of the Serra de Estrella. Lord Wellington accelerated the operations of the siege. On the 6th of April, three breaches having become practicable, orders were given for the assault in the evening. The various divisions passed the glacis under a tremendous fire from the garrison, which greatly thinned their ranks; and they descended into the ditch, and ascended the ramparts, where they were harried by musketry. The Spanish, like harrows, and chevaux-de-frise formed of sword-blades, effectually stopped the way, and the ramparts and neighbouring buildings were occupied by light infantry, who showed their volleys upon the assailants. The English, crossing the river Douro, were then under cover of the cast, and on the 28th the town was stormed, and the garrison of the Douro surrendered. On the 12th of April Lord Wellington moved the main body of his army back to the north, leaving General Hill south of the Tagus. Marmont, on hearing of this, gave up the idea of Almeida and Ciudad Rodrigo, and withdrew to Salamanca. Lord Wellington advanced to Granado, between the Cos and the Agueda, where they remained till the middle of June, nothing of importance occurring in that quarter during the interval. In the south, however, Wellington had reached the Tagus by the 20th of May, the forts which the French had constructed at Almater on the Tagus, where they had a bridge of boats to secure the communication between the Armies of the North and South. On the 13th of June Lord Wellington, having completed his preparations, moved to the plain of Alemtejo, and thence to Alcacer do Sal, and then to the battle-field of Vittoria, where he chose a position somewhat like that of Fontainebleau, with 13 out of 25 of his canteens with about 40,000 men, leaving General Hill on the Tags, near Almarat, with about 12,000 men. On the 17th he appeared before Salamanca. Marmont retired on his approach, and left about 7000 men in some fortresses which were speedily invested by the Allies under hospitalities, and proceeded by the river Tormes. The allied army forced the river and entered the town, to the great joy of the inhabitants. "They have now been suffering for more than three years, during which time the French, among other acts of oppression, expelled them into Spain, broke up 22 of their events, and 22 of their colleges, which existed in this celebrated seat of learning." (‘Dispatches, i. p. 339.) The forts were immediately invested, while Marmont’s army retired to the left bank and crossed the river Douro, and the British advanced up a position on the left of the river Tagus and crossed it, to Fort San Cristobal, which had been fortified. A British division was made to carry the forts by escalade, which failed, and Major-General Bowes and 120 men fell in the attack. On the 20th Marmont moved forward again, and, arriving in front of the forts, which were strongly entrenched with his cavalry in the plain, but ended merely in a skirmish. He made other demonstrations and movements in the following days for the purpose of relieving the forts, but was baffled by the watchfulness of the British general, until on the 24th the forts within Salamanca were taken and surrendered.

Marmont again retired to the Douro in the beginning of July, and took up a strong position on high ground along the norther end of the Douro, his centre being at Tordestillas. One British and Portuguese allied army took up a line on the left or southern bank of the river, facing the enemy. A great deal of manœuvreing, marching, and counter-marching, and changing of front, followed on the part of Marmont, during which the French marshals were reinforced by Desaix’s division, which had arrived from Italy. Marmont had marched over the mountains, having been harassed and pressed by the Spaniards from Galicia under Mahy and Portal. On the 16th of July Marmont threw two of his divisions across the Douro at Toro, when Lord Wellington moved his army, until on the 18th they attempted to cut off the right of the British army, consisting of the 4th and light divisions, but were repulsed by several charges of the British and Hanoverian cavalry, as well as of the British and Portuguese infantry. By his manoeuvres however Marmont succeeded in sinks.
lishing his communication with King Joseph and the army of the centre, which was advancing from Madrid to join him. In the mean time the two armies of Marmon and Wellington were in line on the opposite banks of the Guareña. More manoeuvring took place on the part of Marmon, who, on the 30th, crossed the Guareña on the right of the Allies, and advanced towards the Tormes by Babilafuente and Villamanua. Lord Wellington followed him with his army, and, on the 21st, overtook it near the village of Marmont, and, on the 22nd, occupied the plains of Salamanca, in line of battle. Lord Wellington, in his dispatch to Earl Bathurst dated the following day, July 21, observes as follows—'The enemy's object hitherto has been to cut off our communication with Salamanca and Ciudad Rodrigo, the two chief points of the enemy's retreat. The wheat-harvest has not yet been reaped in Castile, and even if we had money we could not now procure anything from the country, unless we could follow the example of the French, and lay waste whole districts in order to procure a subsistence. Indeed I believe that the French army is the twelfth strongest, and it is certainly equipped with a profession of artillery double ours in number, and of larger calibres. It cannot therefore be attacked in a chosen position without considerable loss on our side. To this circumstance add the disorganisation of our army, especially in the rear, occasioned by the King's, which will be 10,000 or 12,000 men, with a large proportion of cavalry, and that troops are still expected from the army of the north, and some are ordered from that of the south; and it will be seen that I ought to consider it almost impossible to attack the enemy; but I will not hesitate to move them in a new position nearly at right angles with the enemy's line. His cavalry was numerous, and his artillery formidable. Lord Wellington directed a fresh attack, and the 6th division, ascending to the enemy's position under a sweeping fire of musketry, charged with the bayonet, and the 4th division coming up at the same time the French abandoned the ground in great confusion, retreatting towards Alba de Tormes, followed closely by the British till night stopped the pursuit, which was renewed by the ring-bell, led by General Vandeleur. The cavalry came up with the French rear near Laserna, when three French battalions surrendered, being forsaken by their own cavalry. Clausel retired by Peñasanta to Arevalo, whence he took the direction of Valladolid. The loss of the French was 2,153 killed and wounded. The Allied losses were, in general, six field-officers, 130 officers of inferior rank, and between 6,000 and 7,000 men taken prisoners, besides two eagles. Their total loss in killed and wounded could not be ascertained. The Allies had 294 killed and 4270 wounded. It is not possible to attribute to the military and political consequences of that battle the ultimate loss of Spain by the French. (Thiobaud, 'Histoire de l'Empire,' ch. 63.) Among the political consequences must be reckoned the substitution of any tenacious of his party by one with a more moderate character, and the influence of the men in Spain, and even in the Cortes, to give up the English alliance, and make their peace with King Joseph, on condition of his acknowledging the constitution of 1812. The collection of the French in that year. The author just quoted says, 'We are assured that a negotiation to that effect had been entered into, which the battle of Salamanca broke off for ever.'

Lord Wellington, having crossed the Douro, reached Valladolid on the 30th of July, Clausel recommencing his retreat towards Burgos. King Joseph, with all the troops he could muster at Madrid, about 20,000, had marched by the Escorial on the 1st of July to join Marmon. On arriving at Arevalo he heard of Marmon's defeat, upon which he marched thither, and, deepening his retreat, offered a chance of some of Clausel's retreating army. Lord Wellington, recrossing
the Donro, marched against him on the 7th of August, leaving a force on the Donro to watch Clause. King Joseph retreated to Madrid, and the Allies occupied the Guadarrama range of the mountains, the capital and withdrew to the left bank of the Tagus, between Aranjuez and Toledo. Lord Wellington entered Madrid on the 12th, and was received with great acclamations. In consequence of this movement Somosierra, in the Castile line, which the French had constructed with so much labour and expense, and, abandoning western Andalucía, concentrated his forces in Granada. His rear-guard was attacked by an allied Spanish and English force from Cadiz, which drove it from its position in Seville. Wellington, with 70,000 men, had advanced to the walls of Seville at the same time advanced from the banks of the Guadiana to the Tagus, connecting his operations with those of the main body of Lord Wellington's army. On his approach King Joseph abandoned Toledo and fell back to Almansa, in Murcia, to keep himself in communication with Soult and Suchet. A great part of southern and central Spain was thus freed from the French, who never retook Seville; and this was another result of the battle of Salamanca.

The situation of Lord Wellington at Madrid was however critical. Clausey's army had been largely re-inforced, and Soult, and Suchet, and King Joseph, by forming a junction, might advance from the south, and thus the Allies would be attacked by a combined force nearly treble in numbers. In the north the Andalucía line was not more than 6000 men, part of whom were foreign auxiliaries, was cooped up in Alcaniz, and could not effect any powerful diversion. There was no Spanish force of any magnitude upon which Lord Wellington could depend for field operations. The Andalucía line could only be supported by the most effective Spanish corps, after taking Astorga, had advanced towards Zamora, but was driven back by Clausey. Ballasteros, who commanded a Spanish force in Andalucía, refused to be directed by Lord Wellington, and O'Donnell had been defeated in Murcia by disorder and division. At Madrid Lord Wellington was treated with enthusiastic admiration, but no active exertions were made in the common cause. The country was exhausted, the people appeared disheartened, and the British commander-in-chief was possessed of little money, the banks of the treasury, a sum of money adequate to his most pressing wants. To remain at Madrid was therefore impracticable; he must either advance to the north against Clausey, or to the south against Soult, and he determined on the first of these movements, for the purpose of sinking a blow at Clausey before the French in the south and east could advance to his support. Leaving two divisions at Madrid, be marched with the remainder on the 1st of September for Valladolid, who had been defeated by him and driven towards Burgos, was joined at Palencia by the Spanish army of Galicia, which scarcely mustered 10,000 men, undisciplined and deficient in equipment. On the 19th the allied army entered Burgos, and the French, under General Soult, who had been defeated upon the walls of Briviesca, leaving 3000 men, under General Dalretorn, in the Castle of Burgos, strong by its position, which had been fortified with care. The possession of that fort was necessary for the security of the allied army in its present advanced and insecure position, and Lord Wellington directed it to be invested forthwith, though he was ill furnished with siege artillery. A horn-work on a hill, which commanded several of the works of the castle, was carried by assault. The fort itself was battered, but without little effect, and assault was therefore given up. On the 19th his Grace was medically attended in the outer wall by the explosion of a mine, an attempt was made to storm it, but failed. Another breach was effected in like manner on the evening of the 4th of October, and the troops with which were employed within the exterior line of the works of the castle. The garrison made two sorties, by which they materially injured the works of the Allies, and occasioned them great loss. Want of ammunition greatly retarded the operations of the garrison. A breach at last being effected, by mining, the second line on the 10th, orders were given to storm it. A detachment of the King's German Legion carried the breach, and a detachment of the Gardes succeeded in esca- lading the line; but the enemy brought such a fire upon them from the third line and from the body of the castle, and attacked them with numbers so superior before they could be supported, that they were obliged to retire with considerable loss. But now the French army of the north advanced with evident intention to raise the siege; and on the same time Lord Wellington learnt from General Hill, that the Russians and垣is general Ballasteros had not assumed a position in La Mancha, which the Spanish Government, at Lord Wellington's suggestion, had directed him to hold. The British commander was therefore under the necessity of abandoning the siege of Burgos, and of effecting a retrograde movement in order to draw near to General Hill, who was at the approach of Soult abandoned Madrid and retired slowly towards the Tagus.

On the 21st of October the siege of Burgos was raised and Lord Wellington retired in good order to Palencia, and was joined by a brigade from England under Lord Dalhousie, which had landed at Coruña. The French, under Soult, devotedly attacked the rear-guard of the Allies until they reached the Douro at Tudela, when Souham halted, waiting to be joined by Soult from the south. Lord Wellington continued his retreat to the Termes, being joined on the 3rd of November by General Hill. On the 8th of November, the roads were deep and impregnated on the heights of San Cristoval, in front of Salamanca. On the 10th, Souham and Soult joined their forces, which amounted to 75,000 infantry and 12,000 cavalry, while Lord Wellington's army did not exceed 27,000 men, 13,000 of whom were Spaniards. The French crossed the Termes in force near Lucinhos. Lord Wellington took position at the Arapiles, being the ground of his former victory; but as the enemy, through his super- iority of numbers, and especially of cavalry, was in motion to the south of the British force, the Allies withdrew to the Agueda, and on the 18th his head-quarters were at Cindal Rodrigo. Soult did not follow him close; in fact, the French made no serious movement beyond the Termes, and soon afterwards they even withdrew a great part of their army from the left of the river, and fell upon them in better cantonments in Castile. The main army of the British and Portuguese were distributed in their old quarters within the frontiers of Portugal, their left resting at La mego on the Douro, while General Hill's corps moved to Salamanca and the French to S首创 and towards the Tagus, placing strong posts at the passes of Bajas and Bejar. The campaign of 1812 was now terminated. During the retreat from Burgos the allied troops suffered much fatigue and privation; the weather was very inclement, the roads were deep and impregnated with water, and the rivers were greatly swelled, and some of them were breast-high at the fords. Owing to the irremediable difficulty of obtaining provisions in Spain, a great part of the army had neither bread nor salt for days together. The soldiers were compelled to eat which they could not cook, but heated upon such smoky fires as they could make, and so ate it half raw. Many irregularities were committed by the soldiers, which Lord Wellington severely reproved in a circular letter which he wrote to the head-quarters officers of the army, and ordered to be read. Frenas, 26th of November 1812. (Dispatches, i. p. 682.) When the news reached England of the victory of Salamanca, Lord Wellington was advanced in the peerage by the title of Marquis of Wellington, Aug. 18, 1812. On the 3rd of December he received the thanks of Parliament, and on the 7th of the same month the sum of 100,000£ was voted to him as a reward for his services, and to enable him to support with dignity the rank to which he had been elevated.

Campaign of 1813.—Napoleon, having lost the best part of his army in his Russian expedition of 1812, not only could not reinforce his marshals in Spain, but thought it advisable to recall Marshal Soult, at the beginning of 1813, with 40,000 men, to work with his own forces against the allied campaign against the Russians and Prussians in Germany. Soult however only took about 20,000 men with him from the Peninsula. The French had still about 70,000 to oppose to Lord Wellington, and Marshal Suchet, whom the Russians in eastern Spain. The army still called the 'Army of Por- tugal,' under General Reille, had its head-quarters at Valla- dolid; that of the centre, under Dronet, was distributed round Madrid; and the head-quarters of the army of the south, formerly Soult's, were at Toledo. All these forces were under King Joseph, who was assisted by Marshal Jourdan. Clausey and Foy commanded separate divisions in Aragon and Biscay. Andalucía and Estremadura were
Free from the French, as well as Galicia and Asturias in the north.

Lord Wellington had been last appointed by the regency of Spain, with the approbation of the Cortes, to the rank of commander-in-chief of the Spanish armies, and measures were taken to render the Spanish troops more effective than before. A French corps was to join him, the army upon which he could immediately rely for field operations consisted of 65,000 infantry, British and Portuguese, and about 6000 cavalry. With this force he opened the campaign of 1813.

About the middle of May, Lord Wellington broke up from Burgos, crossing the Arga, to the north of the Douro. He marched upon the city of Navarre, and thence to València, taking Pamplona, crossed the Douro, and turned upon the enemy’s lines of communications. He divided his forces, and thus securing the position which the French had taken and had been at great pains to strengthen, along the northern bank of the Douro. The French were taken by surprise, not expecting this movement through Tras-os-Montes towards the north, without meeting an enemy. On the 1st of June, having crossed the Esla, he encamped near Zamora, the French retreating before him, and, being joined by Lord Wellington from Burgos, between the basins of the Duero and the Douro. The capital of Pamplona had been crossed the Douro at Toro on the 3rd of June, joined the rest of the allied army, which was likewise joined by the Spanish army of Galicia, and afterwards by another Spanish corps from the south under Clausel, who, on his way to the army, was dislodged by this rapid march of the Allies, and fearing to be cut off from their comrades in the north, hastily quitted the capital with King Joseph, his court, and retainers, and crossed the Duero at Puente, when the united French army retired to Burgos. Wellington, by marauding in front of the enemy’s right, thus enabling him to concentrate his forces by advancing the French abandoned Burgos, destroying the defences of the castle, and retreated by Briviesca to the Ebro, which was the line they intended to defend. They threw a garrison into the fortress of Panoceño in advance of the French army. The Allies, thus enabled to concentrate their men in forcing the passage of the Ebro in front of the enemy, moved his left by the road to Santander, through a rugged country, and directed it to pass the Ebro near its source by Rocamunde and San Martino, and then to follow the left or northern bank of the river towards Oma. The French position on the Ebro was thus turned, and the French fell back upon Vitoria after an engagement at Oma, in which they were defeated. The whole allied army, having passed the Ebro on the 16th of June, was enabled to take up its position near Vitoria, where the French had taken a strong position in front of the town, covering the three roads from Madrid, Bilbao, and Logroño, which united at Vitoria.

The two hostile armies were nearly equal in number, amounting to 70,000 to 75,000 men each. On the morning of the 21st Lord Wellington moved his army for the attack in three great divisions. The left, under General Graham, was directed by a circuitous movement to turn the enemy’s right by the Bilbao road; cut off its retreat by the Bayonne road; the right, under General Hill, was to commence the action by crossing the river Zadorra where the road from Madrid to Vitoria intersects the river, and to attack the enemy’s left on the high road between the valleys. These divisions, consisting of the 3rd, 4th, 7th, and light divisions, in two columns, was to attack the French centre. General Hill succeeded, after a severe contest, in carrying the heights of Subijana de Alava, when King Joseph ordered his left to fall back fast. Their retreat in good order towards Vitoria, where the French had taken a strong position in front of the town, covering the three roads from Madrid, Bilbao, and Logroño, which united at Vitoria.

When the news of the battle of Vitoria reached England, there were great rejoicings in the camp of the Field Marshal of England, which was appointed to the command of the French army. The French, which was considered an irretrievable disaster, was brought to an end on the 4th July, that the disasters of the preceding campaign were owing to the unskilful councils and unskilful dispositions of their late commanders. "Let us not, however," added he, "defraud the enemy of the peace and prosperity which the dispositions of their general have been prompt, skilful, and consecutive, and the valour and steadiness of his troops have been praiseworthy." He continued by saying that his instructions from the emperor Napoleon to "open to me the most advantageous opportunities to enable him proudly to survey our fertile valleys, and drive them across the Ebro. It is on the Spanish soil that your tents must next be pitched, and your resources drawn. . . . Let the account of your success be dated from Vitoria, and the birth of his Imperial Majesty be celebrated in that city.

Marshal Soult’s first object was to relieve Pamplona. With this view he collected the main body of his army at St. Jean Pied de Port, and on the 20th of July attacked...
with between 30,000 and 40,000 mon, the British right at Roncevaux. General Cole moved to the support of that post, but the French having turned the British position, General Cole considered it necessary to withdraw in the night, and march to Zurbiri. In the meantime two French divisions attacked General Hill's position in the Puerto de Maya, at the head of the valley of Baza. At first they gained ground, but were again driven back, when the retrograde movement was checked. General Hill was at last obliged to dislodge his troops, who being hastily supplied with provisions by their own government, and having the fresh recollection of the treatment which their countrymen in Spain had met with at the hands of the French, could only be retrained by the strongest measures from retaliating the wrongs of 1808. 

On the 10th of November the allied army left their cold and cheerless position in the high valleys of the Pyrenees, pressing on along a difficult and mountainous road. General Hill had a strong position on the Nivelle from St. Jean de Luz to Ainhoa, about 12 miles in length. General Hill, with the British right, advanced from the valley of Baza, and, attacking the French on the heights of Ainhoa, drove them 'round at a curve on the Nivelle, at the rear of their camp. On this the French highly advanced their ground and worked up on the left of the Nivelle, and in the night withdrew to their entrenched camp in front of Bayonne. Lord Wellington's head-quarters were established at St. Jean de Luz on the 13th, when a division of the Spanish army came to the assistance of the Allies; consisting of English and Spanish troops under Marshal BérESCO and General Alten, carried the works behind Sare, and drove the French beyond the Nivelle, which the Allies crossed at St. John's in the night. 

Up to this time the French had advanced their ground and works on the left of the Nivelle, and in the night withdrew to their entrenched camp in front of Bayonne. Lord Wellington's head-quarters were established at St. Jean de Luz on the 13th, when a division of the Spanish army came to the assistance of the Allies; consisting of English and Spanish troops under Marshal BérESCO and General Alten, carried the works behind Sare, and drove the French beyond the Nivelle, which the Allies crossed at St. John's in the night. Lord Wellington, being straitened for room and supplies for his large army, determined to cross the Nivelle and occupy the country between that and the Adour. On the 9th of December General Hill forced the Nive above Cambo, while the 6th division crossed at Ustaritz, and the French were obliged to retire, being cut off from their supply of provisions, which were on the other side. General Hill moved on the place of position, and in the night all their posts were withdrawn to Bayonne, and on the 10th the British right rested on the Adour. On that day Sout, resuming the offensive, issued out of Bayonne, and attacked the British left under Sir John Hope, which covered St. Jean de Luz, when the Allied head-quarters was established at Armenteiras. The French came on with great spirit, and twice succeeded in driving in the fifth division of the Allies, and twice were repulsed again, the first time by the 9th British and a Portuguese battalion, and the second time by the brigade of Guards. 

In the month of October, Lord Wellington moved his left across the Bidassoa upon French ground, and took possession of the hills called La Rhune. The French made only a slight resistance, as Marshal Sout had already fixed upon the line of the river Nivelle in his rear for a position. On the 31st of October the French garrison of Pamplona, 4000 strong, having lost all hopes of relief, surrendered themselves prisoners of war. Early in November Lord Wellington made his preparations for marching his whole army into France, and, after the conclusion of peace, found it prepared for the winter. Before however taking this serious step he issued an order of the day to all his troops of the various nations that composed his army, in which he told "the officers and soldiers to remember that their nations were at war with France since the 14th of May, and that all the time of that period the are to be at peace, and was forced to submit to this yoke; and not to forget at the same time that the worst of the evils suffered by the enemy in his profligate invasion of Spain and Portugal was occasioned by the irregularities of his soldiers and their cruelty towards the unfortunate and peaceful inhabitants of the country. To avenge this conduct on the peaceful inhabitants of France would be unnecessary and unworthy of the allied nations. But Lord Wellington's army was in a state of constant warfare with the general orders; he enforced them strictly and whenever he found any part of his troops attempting to plunder, he not only punished by military law those who were caught in the fact, but he placed the whole regiment or brigade under arms to prevent further offence. His greatest trouble was with the Spanish troops, who being badly supplied with provisions by their own government, and having the fresh recollection of the treatment which their countrymen in Spain had met with at the hands of the French, could only be restrained by the strongest measures from retaliating the wrongs of 1808. 

Nothing of importance occurred during the few remaining months of the year 1813. Both armies remained in winter quarters. On the 1st of January in this year (1813) Lord
Wellington had been gazetted as Colonel of the Royal Regiment of Horse Guards, in place of the Duke of Northumberland, who had resigned; and on the 4th of March he had been elected a Knight of the Garter of the Order.

Campaign of 1814.—The mighty contest which had been carried on for ten years between France and the rest of Europe was drawing fast to a close. The battle of Leipzig, October 16th, had decided the fate of the French Empire. Napoleon had lost another fine army which he had got together with great pains after the disasters of the Russian campaign of the previous year. The scanty remains of his forces were driven out of Germany across the Rhine; that river was to be the barrier of the now desperate Emperor. The natural frontier of France, but which he had not had self-command enough to respect. He was now reduced to the necessity of depending upon the resources of France itself. Wellington had long foretold that such a condition should come to be the test of the future. The Administration would turn against him. Napoleon had hitherto supported his enormous armies chiefly at the expense of foreign states.

On his return to Paris, in November, 1813, Napoleon decreed by a senatus consultum a new levy of 300,000 conscripts. In December he ordered the assembling of 180,000 national guards to garrison the towns and fortresses. He talked however of peace, but he hesitated, and lost time in naming, who had resigned; and on the 4th of March he had been elected a Knight of the Garter of the Order.

Wellington's preparations to drive the army of Soult from the country on the left of the Adour. About the middle of February, by a succession of movements and partial engagements, he drove the French first across the Bidassoa, and afterwards across the Gave de Golfe, an affluent of the Adour. On the 27th of February he met Soult's army concentrated at Orthez on the Gave de Pau, attacked and beat it, and pursued it to the Adour, the French retiring eastward towards Auch. On the 1st of March Lord Wellesley arrived at Bayonne, and the French army was assembled near the town. The loss of the Allies at the battle of Orthez was 277 killed, and about 800 wounded or missing. The loss of the French army was considerable during the battle, and still more during the retreat, owing to desertion having spread to a great extent, especially among the conscripts, who threw away their arms in vast numbers.

The battle of Orthez had important results. The garrison of Bayoue was now left to its fate, and the road to Bordeaux was open to the Allies. Lord Wellington gave orders to General Hougoumont, to detach Marshal Beresford with two divisions to occupy Bordeaux. On the arrival of the Allies at the latter city, the mayor and most of the inhabitants of their own accord, presented themselves to the British officers.

Lord Wellington's business was purely military. In the Spanish peninsula it was to drive the invader out of the country, and leave the people to settle their own affairs. In France, from a similar principle, he was extremely anxious not to countenance the civil war. The Duke of Angoulême having landed in the south of France to excite a movement in favour of the Bourbons, Lord Wellington advised him politicly to keep incognito, and to wait for some more important demonstration in his favour. When Beresford marched to Bordeaux, Lord Wellington directed him not to originate or encourage any rising of the Bourbon party.

"If they should ask you for your consent to proclaim Louis XVIII., to hoist the white standard, &c., you will state that the British nation and their Allies wish well to Louis XVIII.; and that the object of the Allies is to preserve the peace between our troops are stationed, we shall not interfere to prevent that party from doing what may be deemed most for its interest; say, further, that I am prepared to assist any party that may show itself inclined to aid us in getting the better of Bonaparte; that the object of the Allies is to preserve the peace in the war, and above all in entering France, as is stated in my proclamation, Peace; and that it is well known that the Allies are now engaged in negotiating a treaty of peace with Bonaparte; that, however I might be inclined to aid and support any set of people against Bonaparte while at war, I could give them no further aid when peace should be concluded, and I beg the inhabitants will weigh this matter well before they raise a standard against the government of Bonaparte, and involve themselves in hostilities. If however, notwithstanding this warning, the town should think proper to hoist the white standard, and should proclaim Louis XVIII., or adopt any other measure of that description, you will not oppose them; and you will arrange with the authorities the means of drawing, without loss of time, for the arms, ammunition, &c., you will deliver to them. If the municipality should state that they will not proclaim Louis XVIII. without your orders, you will decline to give such orders, for the reasons above stated." (Despatch of 1st March, 1814.)

On the 18th of March Lord Wellington sent his army to Vic Bigorre, and Soult retired to Tarbes, which he abandoned on the 20th, and continued his retreat to Toulouse, where he arrived on the 24th. On the 27th the Allies arrived on the banks of the Gave de Somme. The object of Soult was to facilitate a junction with Suchet, who was withdrawing his troops from Catalonia, in consequence of Ferdinand having been sent back to Spain, and acknowledged as King of Spain by Napoleon, who had reproached this new policy of them in order to waste discord among the Allies. Knowing the character of Ferdinand, he had written to him on the 12th of November 1813, saying, 'That the circumstances of the times made it his wish to conclude at once the affairs of Spain, where England was engaged, with a view to check the depressiveness of the nobility, in order to establish a republic. He (Napoleon) was much grieved to see the destruction of a nation bordering upon his empire, and whose maritime interests were closely connected with his own. He wished therefore to take in the interests of France in such a manner as to interfere in the affairs of Spain, and to re-establish the relations of friendship and good neighbourhood between the two nations.' (Thibaudeau, 'Histoire de L'Empire,' ch. 94.) A treaty was concluded at Valenpaj, where Ferdinand had been made a prisoner for five years, in which Napoleon acknowledged him as King of Spain and of the Indies, and promised to withdraw the French troops from Spain, whilst Ferdinand engaged to cause the English to evacuate the Peninsula.

At last, in the last month of March, Napoleon, being hard pressed for troops for the defence of France, and wishing to avail himself of the army of Suchet, which was uselessly cooped up in Cataluna, allowed Ferdinand to return to Spain. Meanwhile Suchet, who had already detached, early in March, 10,000 men to join Soult, made an offer to the Spanish Regency to withdraw all his garrisons from Catalonia, which were blockaded by Spanish troops, on condition that they be allowed to return to France with their arms. The Regency refused the offer, and Suchet, in pursuance of his own opinion, and he recommended them not to allow any capitulation to any French troops, except on the condition of their being prisoners of war. Suchet's garrisons amounted to about 18,000 men, mostly veteran soldiers, who, if they had been allowed to return with their arms, would have joined to his army. The object was strong for Wellington, a part of whose army was stationed before Bayonne and another part at Bordeaux. Suchet, with his disposable force of about 14,000 men, evacuated Cataluna, and re-entered France. In the beginning of April he placed his head-quarters at Narbonne, but did not join Soult.

On the 10th of April Lord Wellington, having crossed the Garonne the day before, attacked Marshal Soult in his entrenched camp on a range of heights between the rivers Garonne and Adour, near the town of Bayonne, the capital of the department of the Garonne, and the seat of government of the Porc, which they could not be dislodged without artillery. At the same time the Spanish division of General Foy held the attack against the French left with great spirit, but were at first repulsed; one regiment, however, the Tiradores de Castilla, maintained its position under the enemy's canister. The British light division moving up, the whole rallied, and again advanced to the attack. Marshal Beresford, having brought up his artillery, which had been detained by the badness of the roads, continued his movement along the ridge on the right of the French, and General Picton's brigade of the 6th division carried the two principal red-ants and fortified houses in the centre of the French position.
Soult made a powerful attack on the 6th division, which received it with the bayonet, when the French general Tempin was killed. At last the French were driven entirely from the heights, and withdrew across the island of Languedoc into the city of Toulouse, which Soult prepared to defend. The loss of the Allies at the battle of Toulouse was about 600 killed and 4000 wounded. The French acknowledged the loss of 3800 men.

On the 21st of May the 11th Marshal Soult evacuated Toulouse by the only road which was still open to him, and retired by Castelsarrai to Garonne. On the 12th Lord Wellington entered Toulouse, to the great joy of the inhabitants, who were relieved from the fearful apprehensions of a siege, and the fear of their property being sacked, burnt, and cockaded, and the people had pulled down Napoleon's statue and the eagles and other emblems of the imperial government. The municipality of Toulouse presented an address to Lord Wellington, requesting him to receive the keys of the city in the name of the inhabitants. Lord Wellington told them what he had told the people of Bonnereau, that he believed that negotiations for a peace were still being carried on with the existing government of France, and that they must judge for themselves the various prospects of an Armistice of April, to which he had been drawn by the desirability of the Bourbons, in which case it would be his duty to treat them as allies as long as the war lasted; but if peace should be made with Napoleon, he could not give them any assistance or protection afterwards. ('Dispatches,' xii., p. 626.)

On the 10th of May the Jäger, a French military band, was carried off to London by the Adjutant-General Colonel Cooke and the French Colonel St. Simon arrived from Paris, with news of Napoleon's first abdication, and of the establishment of a provisional government in the name of Louis XVIII. From Lord Wellington's head-quarters the two adjutants were sent to those of Marshal Soult, who did not think himself justified in submitting to the provisional government, having received no information from Napoleon concerning what had happened, but he proposed an armistice to Lord Wellington. The British commander wrote to him a very respectful letter, expressing himself as desirous of an Armistice, unless the marshal acknowledged the Provisional Government of France. The object of Lord Wellington was to prevent Marshal Soult and Suchet's armies becoming the nucleus of a civil war in France in favour of Napoleon's pretended brother, and to prevent the amalgamation of the Grand Armies, for pursuit Soult, if required. At last, on the 18th of May, Soult, having received from Berthier an order to stop all hostilities, concluded a convention with Lord Wellington. The British commander had proposed that the Grand Armies should be divided between the two armies. The head-quarters of Lord Wellington remained at Toulouse. Marshal Suchet concluded a like convention with Lord Wellington on the 19th, by which the final evacuation of Cataluna by the French garrison was promised to the British.

Before the news of the events of Paris reached Bayonne, the French made a sortie out of the entrenched camp in front of it, on the 14th of April, and attacked the lines of the Allies, who lost about 600 men in this affair, including General St. Simon, killed. General Suchet, the commander, and Sir John Hope, who was wounded and taken prisoner, General Stopford, of the Guards, was also wounded.

On the 30th of April Lord Wellington set off for Paris, whether he was sent back by Lord Castlereagh. He left General Hill in charge of the army. On the 13th of May he returned to Toulouse, and soon afterwards set off for Madrid, where the army had already taken different sides; O'Donnell and Elío for the king, and Freyre and the Prince of Sangronza for the constitution. Having in some degree quieted the commotion among the army, Spain was joined to the Kingdom into a condition for being amicably settled, Lord Wellington returned to France, and on the 11th of June was again with his army at Bordeaux, giving orders for the evacuation of the city. The troops of the 14th of May he issued his farewell general orders to the army. ('Dispatches,' xii., p. 62.)

In May 1814 he had been created Marquis of Donoro and Duke of Wellington, and the Prince Regent had sent to the House of Commons a message recommending them to grant the Duke such an annuity as would support the high dignity of the title which had been conferred upon him. On the 12th of May an annuity of 10,000l. was granted to him, to be at any time commuted for the sum of 500,000l., which was invested in the purchase of 50,000l. of 6 per cent. annuities. The Duke of Wellington arrived in London, and on the 28th received in his place in the House of Peers the thanks of that House, and on the 1st of July he received likewise the thanks of the House of Commons, through the Speaker.

Peace of 1814.—After the establishment of peace by the treaty of Paris, May 30, 1814, the Duke of Wellington was sent in July as ambassador to the court of France. The Congress of Vienna assembled Nov. 1, 1814, and Lord Castlereagh having returned to England at the beginning of 1815, in order to resume his place in parliament, the Duke of Wellington was appointed to succeed him as the representa- tive of Great Britain. In the month of January 1815 the Duke of Wellington repaired to Vienna to attend the general Congress of the European Powers. In the beginning of March, Napoleon, having escaped from Elba, landed at the head of an army of 20,000 men, at Dunkirk, in order to make preparations for renewing the war in France, without meeting any obstacle, Louis XVIII. having withdrawn to Ghent. On the 13th of March the ministers of the eight Powers assembled at Vienna, including the ministers of the King of France, signed a paper, by which they were to ensure an armistice, and a disturber of the peace of the world, and delivering him over to public justice. ('Dispatches,' xii., 269, 302.) At the same time they declared that they would maintain inviolate the treaty with France, and sent out 60,000 men to occupy the Duchy of Wellington, to which they had appointed to the command of the army to be assembled in the Netherlands.

Campaign of Waterloo, 1815.—In the middle of April the Duke of Wellington repaired to Brussels to prepare for the campaign, and was joined there by the Duke of Baden, who arrived in Flanders, including the Hanoverian Legion, and was joined by the troops of the King of the Netherlands, of the Duke of Brunswick, and of the Prince of Nassau. In all he had had 76,000 men under him, of whom 48,000 were French, and 28,000 Prussians, with their own artillery, and 8,000 cavalry, detached, &c., there remained present in the field about 37,000 British and Hanoverians. The head-quarters were fixed at Brussels. Marshal Bliicher, with the Prussian army, estimated at about 80,000 men, was on the left of the British; his head-quarters were at Mons, in the Netherlands.

During the month of May, Napoleon by great exertions collected an army of about 120,000 men, chiefly composed of veterans, on the frontiers of Flanders; and on the 11th of June he left Paris to take the command. On the 15th the French army was joined by the remnants of the Prussian corps of General Zieten retiring to Fleurus. Marshal Bliicher concentrated his army upon Sombreil, holding the villages of St. Amand and Ligny in front of his position. The Duke of Wellington marched his army from Brussels, and Quatre Bras, on the road from Charleroi to Brussels. Napoleon attacked Bliicher on the 16th, with superior numbers, carried the village of Ligny, and penetrated to the centre of the Prussian position; but the Prussians fought with great gallantry and determination, when Bliicher gave the good order to Wavre. In the mean time the Duke of Wellington, with part of his army, was attacked at Quatre Bras by the 1st and 2nd corps of the French army, commanded by Ney, and a corps of cavalry under Keilermann, which attacked the Prussians of General von Bora. On the 17th the Duke of Wellington made a retrograde movement upon Waterloo, corresponding to that of Marshal Bliicher. He took up a position in front of the village of Waterloo, across the high roads from Charleroi and Nivelles—his right thrown back to a ravine near Montreux, his left extended to a height above the hamlet of Ter la Haye; and he occupied the house and gardens of Hoogvoot, near the Nivelles road, in front of his right centre, and the farm of La Haye Sainte in front of his left centre. The French attacked him at his right, and the Prussians of the 3rd corps, which had been sent to observe the Prussians, on a range of heights in front of the British position.

About ten o'clock on the morning of the 18th of June the French position was occupied by heavy columns of infantry, supported by a numerous cavalry, and by a deadly fire from his nume- rous artillery. His attacks were repulsed with great loss on both sides. In one of these attacks the French carried the post of La Haye Sainte, which was occupied by a detach- ment of the 4th Guards, under the command of Colonel Manteux, who was severely wounded. General Jourdan, whose corps, with his division, were cut to pieces. Napoleon then ordered his cavallery to attack the British infantry, which formed in
squares to receive them, but all the efforts of the French cavalry could make no impression on the British infantry, by whose steady fire they were brought down in great numbers. The French cavalry was nearly destroyed in these attacks, as well as by a charge from Lord E. Somerset's brigade of heavy cavalry, consisting of the Life Guards, the Royal Horse Guards, and the 1st Dragoon Guards, in which the French cuirassiers were completely cut up. At last, by means of a parley and the promise of a complete capitulation, the Prussian corps began to engage upon the French right, Napoleon moved forwards his guard, which he had kept in reserve, to make a last desperate effort on the British left, but, like the army on his left, it was forced back and on the 2nd of July the French began to retire. The British were forced from their position on the heights, and fled in confused masses, leaving all their artillery and baggage on the field of battle. Marshal Blücher now came up with two Prussian corps, and took charge of the pursuit, and though they could not prevent the French from being won at such a fearful cost. The British and German Legion had won on that day 2433 killed, 9586 wounded, and 1876 missing; many of the last however joined afterwards. In the preceding battle of Quatre Bras, on the 16th, they had killed 900 in fight, and 2000 more on the 1st of July, 15,000 killed and wounded, in an army of about 37,000 British and Hanoverians, of whom however about 5000 were not present on the field of Waterloo, being posted near Braine le Comte, or stationed at Brussels, Antwerp, Ostend, and other places. (Official Returns, 'Dispatches,' xlv. 485-87.) More than 600 officers were either killed or wounded at the battle of Waterloo. The gallant General Picton was killed while leading his division to a charge with bayonets. General Sir William Parsons, on a machine gun in the French line, was killed by a party of Polish lancers. Colonel de Lancy, quarter-master-general, was also killed. The Earl of Uxbridge, General Cooke, General Halkett, General Barnes, General Baron Alen, the Prince of Orange, and Lieutenant-Colonel Lord Pitney-Someret, were amongst the wounded. Lieutenant-Colonel the Hon. Sir Alexander Gordon died of his wounds soon after the battle. In the battle of Quatre Bras the Duke of Brunswick Oels was killed, fighting at the head of his corps. Such was the termination of the great conflict, and the end of the terrific warfare of nineteen years from the rupture of the peace of Amiens in 1803.

After the last charge by his guard Napoleon rode off, in the dusk of the evening, from the field of Waterloo, and returned to Paris, which he was soon afterwards obliged to leave. He escaped, except by the short but terrible conflict with the charges of musketry from the British infantry made fearful havoc in their dense mass. They were broken, and gave way down the slope of the hill in irretrievable confusion. On this the Duke of Wellington moved forward his whole army, and the battle on the 2nd of July was conducted in the face of the operations of the Allied Powers.

The Duke of Wellington returned to France on the 28th of August, 1830, to deliver the terms of a treaty between the United Kingdom and the French Republic to the French Government. The treaty was signed at Paris on the 10th of September, 1830, between the United Kingdom and the French Republic, by which the latter agreed to make peace with the former on the terms of the treaty of February 26, 1814, for the restoration of the French Republic, and the evacuation of the French possessions in the United Kingdom, and the other terms of the treaty of February 26, 1814, for the return of the French Republic to its former state of independence and sovereignty. The treaty was ratified by the French Government on the 21st of October, 1830, and the terms were carried into effect by the French Government on the 28th of November, 1830.

The treaty was ratified by the French Government on the 21st of October, 1830, and the terms were carried into effect by the French Government on the 28th of November, 1830.

The Duke of Wellington returned to France on the 28th of August, 1830, to deliver the terms of a treaty between the United Kingdom and the French Republic to the French Government. The treaty was signed at Paris on the 10th of September, 1830, between the United Kingdom and the French Republic, by which the latter agreed to make peace with the former on the terms of the treaty of February 26, 1814, for the restoration of the French Republic, and the evacuation of the French possessions in the United Kingdom, and the other terms of the treaty of February 26, 1814, for the return of the French Republic to its former state of independence and sovereignty. The treaty was ratified by the French Government on the 21st of October, 1830, and the terms were carried into effect by the French Government on the 28th of November, 1830.

in a full House of Commons by a majority of 44. Though the Duke did not approve of the policy of this measure, some of his friends showed him that such a division would be a dividing line in the cabinet and opposition to a declared resolution of the Commons, he yielded, took up the bill, and passed it through the House of Lords, in spite of the desperate resistance of Lord Granville. The bill, which was introduced by Mr. O'Connell, was negatived by 188 to 140. On the 26th of Mr. a motion made by Mr. O'Connor for leave to bring in a bill for the radical reform of abuses in the state of the Catholic population was negatived by 316 to 13; and a motion by Lord John Russell — "that it is expedient to extend the basis of the representation of the people," was negatived by 315 to 117. There we much distress throughout the country among the agricultural and commercial classes, and the body of the people, at that time, appeared to have little to do with the question of a reform of the House of Commons. A change, however, and that sudden and violent about to take place.

The Duke retired on the 26th of June 1830, and was succeeded by William IV., whose political opinions were believed to be more liberal than those of the deceased king, and whose disposition was known to be more amiable and conciliatory. The British parliament was dissolved by proclamation. The constitution and the grievances which excited the members of the House of Commons.

The new parliament assembled on the 26th of October 1830, and the king's speech was delivered by William IV. on the 2nd of November. The debate which followed Mr. Earl Grey, in the House of Lords, urged the necessity of a immediate reform of the House of Commons; and the Duke of Wellington, in reply, affirmed that "the country therefore possesses a legislature which answered all the good purposes for which it was formed and established, and that it is the full and entire confidence of the country," and declared that he was "not only not prepared to bring forward any measure of reform," but would "not resist any such measure as long as he held any station in the government of the country." After these words Mr. Peel immediately rose in the House of Commons, and, after some very interesting and eloquent speeches, the parliament met on the 14th of June, 1831, to pass the Reform Acts for England, Ireland, and Scotland, and Ireland was passed June 7, July 17, and August 7, 1832. The Duke of Wellington opposed the Reform Bills steadily, and sp鬓ately in opposition he became more and more unpopular, and the bitterness of the feeling—at least of the lower orders—may be inferred from the fact, that when returned from a visit to the Tower, June 16, 1832, he was booted and roughly treated by the mob, and would scarcely have escaped with his life had not some gentlemen and soldiers had not placed themselves near his horse, and escorted him. The windows of Apsley House were also broken, and he afterwards protected them by casements.

The office of Chancellor of the University of Oxford became vacant by the death of Lord Grenville, January 1, 1834, and on the 29th of the same month the Duke of Wellington was unanimously elected to succeed him. The ceremony of installation took place on the 9th of June in the presence of the Queen and the Duke of Cambridge.

On the 8th of December 1834 Sir Robert Peel was gazetted as First Lord of the Treasury, and the Duke of Wellington as Secretary of State for Foreign Affairs. This first Reform Act, that of the 29th of March 1832, Lord Grey, who had succeeded Earl Grey as prime minister, assumed the permanent office. William IV., having died on the 25th of June 1837, was succeeded by Queen Victoria, and Le...
Melbourne retained the office of premier till August 30, 1841, when he resigned, and Sir Robert Peel again became prime minister. The Duke of Wellington retorted, however, and under the premiership of Sir Robert Peel resigned office. The Queen then sent for Lord John Russell, but he was unable to form a ministry, and Sir Robert Peel was recalled. The Duke then saw the necessity of the repeal. He put aside his own opinion, stood by his word at Barnstaple, and returned to the Queen and the Commons, and by his influence and his proxies passed the measure through the House of Lords, May 28, 1846, by a majority of 47.

The Duke of Wellington died Sept. 14, 1852, at Walmer Castle, aged 83, as if he had fallen asleep in his chair, after a slight illness in the morning. He was buried in St. Paul's Cathedral, London, under the dome, and beside him remains Lord Nelson. The funeral was public, and the Duke of Wellington had died of natural causes in 1836; and during the procession to the cathedral, Nov. 9, the sympathy of all classes of the people for the loss of the greatest of Britain's military commanders was as strongly manifested as it had been at the funeral of her greatest naval commander in 1837, which was in three Scandinavian countries. It was regarded however as a great triumph of Wellington's views that, in 1837, Sweden conceded the point of allowing a separate national flag to Sweden. It was a result of an interview on Cornwallis between Wellington by his eldest son Arthur, Marquis of Donoughmore, who was born in 1807. The Duchess of Wellington died in 1831.

The leading characteristic of the Duke of Wellington's mind seems to have been sound good sense, based on patient examination into details, and a careful study of the whole in order to arrive at a right conclusion. He made allowance for contingencies, passions, interests, estimated things at their real value, and was rarely wrong. His great principle in his public life was a steady, unswerving, indomitable stimulus of glory or ambition. His manner was in general singularly calm. He never seemed to be elated by success, nor depressed by discouragements or difficulties. Quickness of decision and energy of execution marked his character during the whole of his life. He was not inflexible however in carrying out his plans as a commander or his views as a statesman; but altered his course when new information or a change of circumstances offered a sufficient reason for a change of determination. He was regular in his attendance and punctuality of life, and in his mirth and his cheerfulness. He was a good conversationalist; and at his places in the use of food and wine, slept on a hair-mattress on a simple camp-bedstead, was an early riser, and was indefatigably in his attention to business. He seldom made use of a carriage, and continued to ride on horseback when the froms became of such a height that he could no longer sit erect, and he also used the exercise of walking even to the last, through his steps were slow and altering.

WEGELEND, HENRIK ARNOLD, a very distinguished Norwegian poet and political writer was born on the 17th of June 1806 at Christiana, where his father, Nikolai Wegeland, a clergyman, was one of the assistant masters at the Latin school. The father, who was much expected, and who survived the son, was one of the deputies to the first and second national assemblies in 1814; and the father, who was a pioneer in the movement for union with Denmark and united to Sweden, and met and formed the constitution of Eidsvold, the acceptance of which by Sweden laid the foundation of a new and much more prosperous and glorious period in the annals of Norway. He was afterwards appointed priest of the parish of Eidsvold, the place from which the constitution takes its name, which is at the distance of about 40 English miles from Christiana; and it was there and at Christiana, first at the cathedral school and afterwards in the university, that he received his education. It was in 1826 at Eidsvold that Henrik Wegeland commenced his literary career under the assumed name of Sufi Sifafda, by a farce or dramatic satire entitled 'Ah.' It was afterwards followed by twelve other farces of a similar kind, some in verse and some in prose, and mostly

an Aristophanic vein, with a political bearing and a seasoning of ribaldry and satire. It is not surprising therefore that these productions should arouse the animosity of the parties to whom they referred, and for the ten years from 1827 to 1837 Wegeland's life was passed in what is familiarly called 'turbulent water.' But his was not the fate of all. Some of his works in prose, some of which he occasionally edited, were not very frequent; and his poems, many of which were on political subjects, were hardly less numerous. His admirers were at this time fond of calling him the 'Byron of Norway'; but his 'R. G. Laslett, who knew him, says that he was better regarded in Norway, and so narrow as to be antagonistic even to the other members of the Scandinavian family, the Danes and Swedes. For some time he drew the whole youth of Norway with him, but in 1838 the appearance of an attack upon his best work and even another run of post and press by the 'Henrik Wegelands Digteksent og Folkemik' (Henry Wegeland's Poetry and Polemics)—began to turn the current, though Wegeland's father wrote vigorously in his defence, and at present it may be considered that the public regard for his work is passing away from him. His success, however, has been very great in the kingdoms of Sweden and Norway, and his admirers have been very numerous in all three Scandinavian countries. It was regarded however as a great triumph of Wegeland's views that, in 1837, Sweden conceded the point of allowing a separate national flag to Sweden. It was a result of an interview on Cornwallis between Wellington by his eldest son Arthur, Marquis of Donoughmore, who was born in 1807. The Duchess of Wellington died in 1831.

A collected edition of the principal works of Wegeland was commenced in 1851 by the Student's Society of Christiania, under the editorship of H. Lassen. The last volume we have seen of it is the eighth, published in 1856, and it was to be completed in nine. The editor, who had the task of collecting many of these writings from magazines, reviews, and newspapers, had this task been not always easy, for on some occasions it was necessary to render them intelligible to those not intimately acquainted with the passing history of Norway at the time during which they appeared. Three volumes of the eight are occupied with poetry, among which is Jan Van Huygen's Flower-Pieces, and the Fourth Stuarts are considered by far the best. One volume is filled with farces; two others with dramatic poems. An early tragedy, entitled 'Sinclair's Death,' is founded on a well-known incident in the annals of Norway; the story of the Sortland mercenaries in Sweden by a treacherous attack of the Norwegian peasantry. An opera entitled 'The Campbellers,' and two tragedies, 'The Child-Murderers' and
The Venetians,' are of particular merit. 'Creation, Man, and the Messiah,' is given in a revised and corrected shape, as left by the author. Of Weergeland's prose writings the most interesting are a volume of short biographies of distinguished persons, and a history of the constitution of Paisley.

WERNERITE. [SOAPOLITE.]

WESTALL, WILLIAM, A.R.A., younger brother of Bowen, was born at Hertford on October 13, 1781. He studied at first under his brother, and subsequently at the Royal Academy. Here however his studies were interrupted, by his appointment, in 1801, on the recommendation of the President, West, to accompany Captain Flinders in the "South-Wind" on his important mission to the southern seas. Westall was with Flinders for two years, when, the Investigator having been abandoned, he was transferred to the companion ship, the Porpoise, in which he was wrecked on a coral reef on the north coast of Australia on his voyage home. Thus he, who had been on a voyage of discovery and had seen the coast and the interior of Australia. Of these he exhibited at the Royal Academy, in 1812, his views of 'Port Bowen,' and 'Seaford's Isle in the Gulf of Carpentaria;' and the striking character of the scenery, and the rich and novel herbage, which he had himself collected, and prepared them very attractive. They secured his election as Associate of the Royal Academy in the same year: he had for some time previously been a member of the Society of Painters in Water-Colours. Unfortunately perhaps for his reputation, he did not stay at Sydney, and he had thus opened. He turned his attention to making drawings for engraving, in which he for many years found ample and profitable employment, but he thus contracted a neatness and prettiness of style which proved destructive of all grandeur of effect when furnishing in his paintings. Among his best known series of engraved designs are his views of the lakes of Westmoreland and Cumberland, which are drawn with great fidelity, though with some deficiency of power: he was a frequent visitor to this district, and the enjoyment of it by Sir Walter Scott, has been a theme for Wordsworth, by both of whom he was greatly esteemed. He also drew and engraved in aquatint a series of views of the Caves, and of the Abbeys and other Monastic Ruins of Yorkshire, of the Isle of Wight, Oxford, Cambridge, the Rock of Cashel, and Poets' Corner at Westminster. Of his collection of oil paintings to the exhibitions of the Royal Academy were comparatively few, and in his later years they became fewer than they might else have been, from finding himself in reality excluded from the full honours of that institution. Mr. Westall met with a severe accident, in 1847, by which his left arm was broken, and he received some internal injuries, from the effects of which he never wholly recovered. He died January 29, 1850.

WESTERN AUSTRALIA, in its widest sense, extends over that portion of the continent lying west of the 123° E. long., the boundary west of South Australia and North Australia; so that the boundary-line between it and the other parts of the continent joins the Indian Ocean east of Cambridge Gulf, and separates it from the Great Australian Desert. Thus Western Australia contains about one-fourth of the whole continent, and lies between 30° and 14° S. lat., 115° and 123° E. long. The limits of the British colony, originally established under the name of Swan River Settlement, are much less, but the boundary has not been definitely settled, and is constantly being extended. It may be said to lie between 30° and 35° S. lat., 110° and 119° E. long., or about 400 miles from south to north, and about 260 miles in breadth. Geology.—The coast-line presents a much greater variety than most other parts of Australia. In some parts the sea to some distance from the shore is covered with numerous islands, islets, and rocks, which render these countries difficult of access. From this cause an extent of coast-line, about 600 miles in length, has not been visited. Thus there is a coast distance of nearly 3500 miles, so that our information in respect of the natural products of the country is very limited. Within the confines of the colony there are numerous estuaries, each of which receives several rivers. Of the few good harbours along this coast is Broome Rockingham in Cockburn Sound, Albany in King George's Sound, Bunbury in Port Lechenhaut, and Augusta, near Cape Leeuwin, on the southern side of the south-western promontory of the island. At the mouth of the Swan River, and at the head of the Melville Water, which runs inland near the north-west coast, is the capital of Western Australia. The entrance is encumbered and rendered dangerous by several rocks. A lighthouse is placed on Rottnest Island at the entrance, and on some of the more dangerous rocks there are beacons.

MOUNTAIN SYSTEM.—The Darling Mountains extend along nearly the whole length of the colony. Its distance from the coast varies from 50 to 150 miles, and its height is from 800 to 3000 feet. It is generally sterile; the granite appears in some places in masses of unbroken rock, and plane the surface resembles the English heath grow in considerable numbers. There are forests of large mahogany and blue gum-trees. In the Darling Mountains have been found roofing-slate, lime-stone, marl, and some granite. The rock is composed of an aggregate of iron-ore, chamois of lead, galena, and copper. Wide valleys bordered by fertile plains occur where basaltic rocks are developed. Columnar basalt is found around Geographe bay, and from thence to Shark Bay a band of coal has been traced a distance of 60 miles west of the colony.

In that part of Western Australia which borders on the south coast, there are three distinct parallel ranges of mountains running from north to south. The highest and most eastern of these has its southern termination near King George Sound, at Cape Naturaliste, 30° S. lat.; and Cape Chatham, 32° S. lat.; Cape Leeuwin, in about 34° 20' S. lat., is the southern termination of the third range, which is inferior in altitude, as well as in extent, to the other two: it terminates on the north at Cape Naturaliste, 30° 27' S. lat. The highest point of Western Australia is Mount Wellington, which is situated on an elevation of 5000 feet. On the mountains and higher hills the surface is rugged and stony; on the lower sides of both the soil is excellent; but in the principal valleys and the lower grounds, where the sandstone formation prevails, it is of a very poor quality: the box-tree, or acacia, is the principal tree, the trunk of which is 20 feet in diameter, and the height 100 feet. The Swan River rises on the western side of the Darling Range. At its mouth is a bar, after passing which the river is navigable, though with difficulty, for some distance. The other rivers are the Avon, the Murray, the Cann, the Harvey, the Preston, the Collie, the Vasse, the Margaret, and the Murray. The Darling River is chiefly navigable for only 2 miles: the Swan rises in the Darling Range: it is smaller than the Swan, and only navigable for a few miles. Shoals impede the navigation, and in dry weather boats must be pushed over them for fully half a mile. The Murray takes its rise also in the Darling Range. At its mouth, which is situated at an elevation of 6000 feet, the river is very shallow.

For the botany and zoology of Western Australia, see Australia.

Climate.—The climate of Western Australia has the same general character as that of Eastern Australia. [AUSTRALIA.] It has not generally been found prejudicial to Europeans, but in the case of some persons it has caused them to feel the disadvantages. Though variable, the western part of this colony...
It has a jail, and some trade in timber. Augusta is a small port on the eastern side of Cape Leeuwin, on the estuary of the Blackwood River. Bunbury is the port town of a district formerly called Australind, of which a small village by that name is the nucleus; and to which, upon which it stands, is a good and large one, but it has little commerce. Geraldton is an inland town on the Murchison River, founded in consequence of the commencement of the working of lead-mines there by a company. Guildford is a town of considerable importance, of which more is said anon. Northam is a small inland town, in an agricultural district, east of the Darling Range, on the river Mortlock, and is about 60 miles in a direct line E.N.E. from Perth. Rockingham is on Cockburn Sound, and has a good port, and some emigration. The port of Fremantle, about 50 miles from Northam, and about 50 miles N.E. from Perth, upon the river Toodyay, which pierces the Darling Range, and falls into the Melville Water, but is not navigable. Vasse is a small port on Vasse Inlet, in the centre of Geographe Bay, and where, about 90 miles S. from Vasse, across a fine country, forming the promontory bounded by Cape Leeuwin and Cape Naturaliste. Other small towns of little importance are named York, Picton, Carnarvon, &c.

WESTMACOTT, SIR RICHARD, R.A., was born in London in 1775. His father was a sculptor of some eminence in his day, and in his studio (Mount-street, Grosvenor-square), the young Westmacott learned the use of the chisel. On the 1st of March, 1793 he was admitted into the Royal Academy, and received instruction from Canova. His career as a student in Italy was a distinguished one. He carried off the first prize in sculpture at the Academy of Florence, in 1794; and in 1796 the medal given by the pope. He was elected a Member of the Royal Academy of Fine Arts of Paris, in 1797. But what prolonged stay in Italy, he returned to London, and was soon recognised as one of the best of the young sculptors of the day; and his future career was on the whole a very prosperous one. His imaginative works were of an exceedingly graceful and poetic tendency, and in execution resembling that of the modern Italian school; several of these will retain their place among the best poetic works of the English school of sculpture. The most popular is his veined plaster of 'Psyche,' exe- cuted for the Duke of Bedford, and now, with other marbles, 'Cupid,' at Woburn. Among the best known of his other poetic works are the 'Euphrasion,' executed for the Duke of Newcastle; an exquisite figure of 'A Nymph unclasping her Zone,' the property of the Earl of Carlisle; 'The Distressed Mother,' executed for the Marquis of Lansdowne; 'The Homeless Wanderer;' 'Devotion,' &c. He also exe- cuted several important works in altar and bas-relief; one of the first of which was probably his portion of the frieze of the mosque on the Mausoleum of the Sultan of Odessa. Several of other portions being Flaxman and Baily. His latest work in this style was the pediment of the British Museum. He also executed for the late Earl of Egremont, a large altar-relievo in marble of the 'Death of Horace' for the gallery at Petworth. A large part of his time was however occupied, and much of his reputation now rests, on public monumental statues. Of these it will suffice to mention his statues of Pitt, Fox, Spencer Perceval, and Addison (1800), which, with his monuments of the Duke de Montespennes, of Mrs. Warren, and her Child, the Duchess of Westminster's Abbey, and Sir Ralph Abercromby, Lord Collingwood, and Generals Pakenham and Gibbs, in St. Paul's Cathedral; Lord Erskine in the Old Hall of Lincoln's Inn; Fox in Bloomsbury- square; Florence Nightingale in St. Thomas's Hospital, and the Duke of York on the column at Waterloo-place. The so-called 'Achilles,' copied from the statue at Monte Cavallo, Rome, and inscribed by the Women of England to the Duke of Wellington, was modelled by Westmacott, but whether he had any hand in it to be decided. It is manifestly his taste, or that of the women of England, we do not know.

Westmacott was elected A.R.A. in 1806, and R.A. in 1816. In 1837 he succeeded Flaxman as Professor of Sculpture at the Royal Academy, which office he held till his death. He was a man of extensive reading and sound judg- ment, and his lectures were marked by these qualities, and by the absence of pretension. Shortly after her accession to the throne, her Majesty conferred on him the honour of knighthood. He died on the 1st of September, 1856.
and writer on international law, was born at Providence, Rhode Island, U.S., in November 1785. Having completed his education at Brown University in his native city, he graduated there in 1802; studied law under Mr. N. Sere, and was admitted to the bar. He then passed a couple of years in Paris and London, during which he acquired considerable acquaintance with the French language, and rendered himself a complete master of the French language. On his return to America he settled in New York; commenced practice in his profession, and in 1812 became editor of the 'National Advocate,' which journal he continued to conduct for about three years. He contributed to it, among other things, a series of disquisitions on the law of nations. In 1816 he was appointed one of the justices of the Marine Court, and the same year he published a 'Digest of the Laws of England, as affected by the war with France.' The work was received by the profession with much favour. He was about this time appointed reporter to the Supreme Court of the United States, an office he held for twelve years; his 'Reports of Cases Argued and Determined in the Supreme Court of the United States during the Tenure of the Hon. William Cushing, Judge of the said Court,' was published in 1818. This work was taken as a model by the judges of the courts of the United States, and has been continued to the present time.

WIDIN, a fortified town in Turkey, capital of Upper Bulgaria, is situated on the right bank of the Danube, opposite the straggling village of Calafat on the left bank, about 130 miles E.S.E. from Belgrade, and has a population of about 3000. The town is of great antiquity; it was founded by the Turks in 1853-54. The town contains pretty wide streets for a Turkish town; many mosques surmounted with graceful minarets; small bazaars, &c. It is the residence of the Austrian Danube steamer company. The trade of the town is in rock-salt, corn, wine, and agricultural produce. The Austrian Danube steamer company put into Widin. The inhabitants of Widin consist of Turks, Greeks, and Armenians; the Christians inhabit suburbs outside the walls of the town.

WIFE AND HUSBAND. The chief alterations in the laws affecting the relation of husband and wife have been already stated, but may be shortly summed up in this place. A wife was deserted by her husband may obtain an order for a separation on the ground of cruel or inhuman treatment, or she might be then be able to contract as if she were a femme sole (20 & 21 Vict. c. 85, s. 81). When the desertion of the husband extends over a period of two years, or when he treats her with cruelty, or commits adultery, the wife may obtain a divorce, of which he may not obtain a re-admission, but which commits incestuous adultery, or to adultery adds the crimes of bigamy or rape, cruelty or desertion for two years, or is guilty besides the adultery of an unnatural offence, the wife may obtain her freedom by paying the damages, and cannot apply for a divorce. This Act 20 & 21 Vict. c. 85, which has effectuated these alterations in the law, makes various other provisions, for which however the statute itself must be referred to.

WIFFEN, JEREMIAH HOLME, was born in the neighbourhood of Wick, in 1792, of Quaker parents, and was educated for the profession of a schoolmaster, a vocation which he followed for several years. He very early however displayed a taste for poetry and literary composition. In 1813 he published a 'Geographical Primer,' and in the same year, through his own exertions, he published a small and learned work on the role of the Scandinavian history and literature, the result of which he published in London in 1815. He was afterwards, in 1817, appointed Professor of Scandinavian History in the University of Jena, and continued in the same capacity until his death.
though with pardonable partiality. He lasterly studied Hebrew and Welsh, from the last-named of which he made several successful poetical translations. Mr. Willemin entered his connection with the Society of Friends, holding offices of trust in it occasionally, until his death, which took place suddenly on May 9, 1866, at Woburn Abbey.

WILL AND TESTAMENT. The 'Wills Act,' 1 Vict. c. 36, has been amended by the Statute 16 & 17 Vict. c. 34. Since the last-named measure an immense number of questions had arisen upon the language of its provisions; and probate had over and over again been refused to wills, the authenticity of which was beyond all question, on the ground that the words used by the testator were not the words, or were not a specimen of legislation; as the simple perusal of it will show, that it is not passed to amend the law, but to provide against the consequences which have been held to follow from the negligence of testators, in not paying strict attention to that very element of the Wills Act, which requires the instrument to be signed at the "foot or end."

WILLEMS, J.AN FRANS, the originator of what is called "the Flemish movement" for the revival of the cultivation of the Dutch language in Belgium, was born at Bonchoot, a village near Antwerp, on the 11th of March, 1793. The French sans-culotte army, under Dumouriez, was at that very time advancing to the siege of Antwerp; a party of his soldiers entered Bonchoot on the night that Willems was born, and on hearing the state of affairs politely withdrew from the town. He was the first child born in the city, and little foreseeing how effective an opponent he would prove to the influence of France in Flanders. The attachment of Willems to the Flanders language, and his whole life, has been described by Lierre, where he had resided from the age of twelve to fifteen, then the young Willems sang and playing on the organ, and where he was fortunate enough to meet with a protector and educator in the person of Mr. Bergmann, who, in the then cessation of public means of instruction, was the only leader in his own family, and allowed young Willems to share their instructions in Latin and literature. Lierre was still in possession of some of the 'Rédéryk-Kammers,' or Chambers of Rhetoric, the existence of which was one of the most famous literary features of olden Belgium. He was enabled by this to get up theatrical entertainments. "The Cecilian Society of the principal church, St. Gummar's, where I every day sang or played the organ, being," says Willems, in a history which he afterwards wrote of the Chambers of Lierre, "in the mind to act some pieces for the benefit of the church, this was the occasion of first bringing me on the stage, and I represented the angel Gabriel bringing the announcement to the Virgin Mary, in the piece entitled 'The Nativity and Youth of Jesus Christ.' I remember that our manager, Mr. Van den Bussche, a retired publican, came to me every evening before the curtain rose made us kneel down on the stage, and read the Litany of Our Lady that the performance might go off well. It was strange to see how all the multitudes that came to see the spectacle, the King, St. Joseph and our Lady (N.B., our Lady with a beard), Herod, the three kings, the Jewish Scribes and Pharisees, the angels and the devils all joined in the responses, 'Pray for us, pray for us.' I shall never forget it." The mysteries of the middle ages were then as yet not seen, flourishing in the 19th century in Belgium, as well as in some more remote corners of Europe.

When Willems was a boy of fourteen at Lierre he wrote a poetical satire in Flemish on the authorities of Bouchout, which he entertained, or rather got his father to entertain, as a tax-collector. This and some other proofs of talent led his patron Bergmann to advise his parents not to bury him in the obscurity of his native village but send him to Antwerp, where he was placed as clerk to a notary, and, in 1816, commissioned with the duty of getting up theatrical performances of the prize that was offered for the best poem on the battle of Friedland and the peace of Tilsit. An amateur theatre was his favourite recreation, and two plays of his composition, 'The Rich Antwerper and the Quaint Merchant,' met with success both on the stage and elsewhere. The union of Belgium with Holland, which followed the overthrow of the French dominion in both countries in 1814, naturally directed attention to the fact that the so-called Flemish language had been twice levelled by the French, and was steadily rising again. Willems, who was no writer in his own language, and who was always ready to lend a hand with the cultivation of the Flemish language, which was at one time more cultivated in Flanders and at another in Holland. Willems took the lead in reviving and making permanent what it is very singular should ever have been overlooked or forgotten. A spirited poem by him—'Aen de Belgien!' (To the Belgians)—published in 1816, exerted his countrymen not to continue to abandon the language of their fathers, which was also the language of Vondel and Bilderdyk. This poem, which produced a strong sensation, was accompanied by a French translation, which it may be remarked was not a very faithful one. It excited the attention of the Royal Academy of Language and Literature in connection with the Southern Provinces of the Netherlands.' (Verhandeling over de Nederlandsche Tael- en Letterkunde opgetekent by de Zedegelyke Provincien der Nederlanden), which was commenced in 1819 and completed in 1836, in four large folio volumes, aimed at tracing the literary history of Flanders and Brabant from the 13th to the 19th century, showing that literature had flourished in those countries as long as the language, and that it had declined since the religious wars which led to the separation of the North and the South Netherlands, because from that period Latin, and particularly French, had been looked upon as the only instruments of literary cultivation in the Catholic Netherlands, while the use of the native dialect, or of one nearly akin to it, had been abandoned to the Protestants of the Seven United Provinces. There was an outcry against the author of this work on two accounts, one from the antagonists of the union of Belgium with Holland, who deprecated the views of Willems, and another from his views tended to recommend the government measure of the introduction of Dutch as the official language, the other from zealous Catholics, who were indignant that a Catholic should maintain the superiority of the literature of the Protestant portions of his country. Willems then, in his last-named works, had great value at the time of its appearance as the only attempt at a connected history of Flemish literature, but the additional light since thrown on the subject by the researches of Willems himself and of several others has had the effect of rendering In the degree of interest of its publication Willems was looked upon as the champion of the Flemish cause, which he defended against all enemies and in particular against Van de Weyer, a French pamphleteer, who published a Flemish dictionary in 1829, only a year before the violent secession of Belgium and Holland.

The revolution of 1830 appeared at first sight to be a mortal blow to the prospects of the Flemish language, and also to the future of its patron Willems, who was then placed by the Dutch government in the advantageous post of a receiver of some public dues at Antwerp, where he had been previously appointed by the city as an assistant keeper of archives. He had also been, in conjunction with Van de Weyer, one of the founders of the Flemish monasteries of the South Netherlands. Of these posts he was deprived by the provisional government of Belgium, and sent in an obscure position, with a reduced salary, to the small town of Eecloo, where, declining the offers of the Dutch government to place him in a more advantageous position in Holland, he remained for four years. By that time the indignant remonstrances of some of the chief literary men of Belgium, and in particular of his old opponent Van de Weyer, aroused the government to a sense of his unworthy treatment, and in 1836 he was placed at Ghent in a situation similar to that he had occupied at Antwerp. While at Eecloo he had published a modern Flemish version of the celebrated medieval poem of 'Reynard the Fox,' which he had translated from the old Flemish manuscript, and which was a success in London. This, together with the hope of an old Flemish manuscript of the poem at London, in the auction of Richard Heber's library, he applied to the Belgian government to secure it for Belgium; it was purchased at his recommendation for 1865, and in 1856 the poem was printed under his supervision. To his enterprise and perseverance is due the preservation of so much interesting matter. The cultivation of the Flemish language, which he had first promoted, went on increasing. In 1841 a Flemish festival was held at the University of Ghent;
two years later a meeting of the 'Taelverbond,' or 'Language Association,' at Brussels, at which Willems officiated as president. The movement was too powerful to be withstood by the government. Willems had no longer to fear disgrace for his exertions, and had already, in 1838, been named a knight of the order of Leopold. The Flemish movement still appears to mark progress, and the meetings which have been held of distinguished literary men of both the North and South Netherlands appear likely to result in placing the Flemish in a position of esteem and recognition which it has never enjoyed for centuries. Willems however was not destined to witness this triumph. He died at Ghent on the 29th of June 1846, after a very brief illness, of an apoplectic attack.

His works, according to the list given in the 'Belgisch Museum,' are 43 in number, 35 in Flemish, 5 in French, and the remainder in both languages. The most important which have not been already mentioned are his 'Mengellingen van een inheem cin' (Miscellaneous on National Subjects), Awtwerp, 1875-76; the 'Rymed Chronicle of Jan van Heeuf,' and the 'Rymed Chronicle of Brabant, by Jan de Klerk,' edited for the Belgian Historical Commission; and the 'Chronicle of Edward the Third, king of England, written in the Congress in Jan de Klerk,' and first published by Willems at Ghent in 1840.

WILLIAM II. (FREDERICK GEORGE LOUIE), King of the Netherlands and Grand Duke of Luxembourg, was born on December 6, 1782, and under the care of his father, Prince Leopold, the infant was completing his education in the university of Oxford, where he showed much talent. He entered the military service early, serving his first campaign with the English army in Spain, and in 1811 accepted the rank of lieutenant-colonel in the Spanish army. His early achievements and success gained him the esteem of the Duke of Wellington, who made him his aide-de-camp. At the siege of Ciudad Rodrigo he was among the foremost in the storming party, and at that of Badajoz he exhibited qualities of courage and determination which attracted his father's attention. In 1815 he commanded the army of the Netherlands, and displayed bravery and military skill in the battle of Quatre Bras, and in that of Waterloo, at which he headed his troops, and was wounded in the shoulder. On his recovery he was recalled to the command of the army of Holland in the short war against Belgium, in which he was at first victorious, but was at length compelled to retreat by the armed intervention of France. He was then appointed to the command of the army of observation on the Belgian frontier. On the resignation of his father in 1840, he resumed the government, in which he showed great regard to economy, and a desire to promote financial improvements, but opposed all constitutional reforms. On the breaking out of the revolutionary storm, which spread so widely throughout Europe in 1848, he preserved the loyalty of the government, probably might have been avoided by smaller concessions made earlier. He did not however live to witness the effect of the alterations, as he died on March 17, 1849.

WILLIAM, SIR, a skillful designer and engraver on wood, was born at Colchester, Essex, on the 23rd of February 1788. The son of parents in humble circumstances, his early desire to become an artist met with little encouragement; but he taught himself to paint, and in his native town. While serving his apprenticeship however

he taught himself etching, and subsequently wood-engraving. So attached had he become to the latter art, that on the expiration of his term of service he determined to adopt it as his calling, and, possessing some skill in design, he found ready access to the London publishers of low-priced works. His earliest works include: a series of 300 plates was given into the hands of the then untried country artist. Gradually increasing his number of clients, and being perhaps the most original among the best designers and wood-engravers of his time. His earlier engravings executed for Whittingham's Novelties and Poets, for Willem's 'Tasso,' and the architectural publications of Mr. J. Britton, displayed great freedom and ability in the treatment of their subjects. He afterwards appeared in the capacity of a designer, and original, though occasionally somewhat rude designs were made for Hone's 'Every Day Book.' In his later engravings and designs as those in 'Howitt's Rural Life,' 'Scrope's Days of Salomon-Taylor and Beer Staking,' 'Bathg Examined,' 'Seasons,' &c., he shows much more elaboration and neatness, with an equal evidence of the devoted study of rural life and scenery, but perhaps some loss of power. Through out life he retained his early ambition of painting in oil, but was not successful. He graduated B.A. in 1807, works of 610 kilos in that branch of art. He died on the 19th of September 1853. Two of his sons still sustain the reputation of the name of Williams as wood-engravers.

WILSON, PROFESSOR JOHN, was born on the 19th of March 1766, and was educated at the University of Edinburgh. His father was a wealthy manufacturer. He was the eldest son: one of his brothers, James, became distinguished as a naturalist; one of his sisters became Mrs. Ferrier, and the mother of Professor Ferrier of St. Andrews; and another of his sisters married Sir James Watt, the inventor. A pupil and essayist was sent to a school at Glenorchy in the Highlands kept by the Rev. Dr. Joseph McIntyre; and here he acquired his first enthusiasm for Highland scenery and his love of open exercise, and at the age of thirteen he went to the University of Glasgow, whence, after five years of study, he removed in 1803 to Magdalen College, Oxford. At Oxford he was distinguished no less for his literary genius and attainments—as shown in his carrying on, among other honours, the biographical prize in 1806 for a poem on 'The History of the Decline and Fall of the Roman Empire.' From the age of nineteen he was on the study of Greek and Roman Architecture,—than for the exuberance of his animal spirits, his great physical strength and beauty, and his fondness for athletic sports. He was the best boxer, leaper, and runner about the University. He graduated B.A. in 1807, and in 1814, with the degree of M.A. "A fair-haired Hercules- Apollo," says a writer, sketching his life at this time, "and with plenty of money enabling him to gratify his tastes whatever they might be, he had scarcely left Oxford, when he signified his intention of engaging in the wars of the First Consul, which he did by his father, the small, but beautiful estate of Eilean on Lake Windermere, where as Hercules, he might yacht about at his pleasure, heat the best boatman at the oar, and wrestle with the smartest blacksmith. What the Hercules of Greece might do in the quiet beauties of the finest of English lakes, he might revel in, indisput undisturbed in poetic dreams of his own, and cultivate with due reverence the society of Wordsworth." Here, besides Wordsworth, he became acquainted with Coleridge, Southey and De Quincey, the last of whom describes the extraordinary manliness of his character at this time, dashed with an eccentricity which showed itself in all kinds of freaks and projects—and among them that of becoming a traveller in Africa. It was at this time (1810) that he entered the service of Sir Henry Clinton, who had been sent out to the Mediterranean, and who was a visit to the Lakes with her family, and, falling in love with her at first sight, wood and won with romantic rapidity. He had by this time published some anonymous works, written in Coleridge's 'Friend,' and elsewhere; and in 1811 he published his first essay in poetry, which piece, dedicated to the Memory of the Rev. James Grahame,—i.e. the poet Grahame, the author of 'The Sabbath.' Though his summer head-quarters were at Eilean, Wilson spent part of every year in making a tour, and during one of these tours a letter from a letter to Miss Joanna Baillie will show the impression which he had begun to make in Edinburgh: "The author of the Elegy upon poor Grahame is John Wilson, a young man of very considerable poetical powers. He is now engaged on a poem, which promises to bring him into prominent notice."
burgh, where he now is. ... He seems an excellent, warm-hearted, and enthusiastic young man; something too much perhaps of the latter quality places him among the list of originals." The 'Isle of Palms' here alluded to, was published in 1812, and gave Wilson a place among the Lake Poets, the 'Poets of Passion'; but this is no admired, however he never practised; and from that time forward Edinburgh was his accustomed place of residence. He wrote for the 'Edinburgh Review' a criticism on the 4th canto of Childe Harold—his only contribution to that periodical. 'On the Enchanted Isle' is a poem of some length, on 'The City of the Plague'; his magnificent physique was the admiration of Edinburgh, so that, as he walked hurriedly along Princes-street in somewhat wild costume, and with his fair hair streaming from under his broad white hat, he was the centre of all the circles that was that of a young Goth of geniuses with Powers undeveloped, which would one day astonish Britain.' At first Wilson was associated with Lockhart and others in writing for the 'Quarterly Review,' and that is what led him to the conclusion that publication was identified with him to that full extent.

The connection with Blackwood was an important event in the life of Wilson; and it was speedily followed (1820) by another important step in his political and literary career. Hamilton, afterwards Wilson's colleague, was a defeated candidate on the occasion. Scott, who used all his influence in behalf of Wilson, wrote to Lockhart expressing his hope that if he obtained the appointment, it would give him "the confidence and steadiness of character" which are all he wants to make him the first man of the age." The appointment, together with his connection with Blackwood (both of which came at a time when some pecuniary reverses had checked his career and driven him into the life at which he had, at all events, the effect of determining Wilson's genius permanently to prove rather than to veer. He still, indeed, wrote verse in the Lakist style in quantity sufficient, when added to what he had already written, to make two octavo volumes. His son, Sir Thomas Wilson, in 1831, in a poem of some length, called 'The Trials of Margaret Lyndsay.' He wrote also political articles on the questions of the day, in which he blazed out as a Tory in a manner heartily satisfying to his instincts, and yet as a liberal in his powers of eloquent desultory and detached criticism, in which he advanced and expanded canons of taste, especially in poetry, deeper than those of Jeffrey, and vindicated against that critic and his disciples the poetic claims of Wordsworth and the writers associated with him. He wrote, either as lectures or as articles, subtle philo-
sophical disquisitions, not very connected or systematic perhaps, but gleaming with brilliant ideas, and tinged throughout with that rich and highly-coloured mode of metaphor which Coleridge was diffusing through England. Lastly, careless of the formality conventionally identi-
tified with the gown of a Scotch professor, and that the gown of a professor of moral philosophy, he wrote papers for the magazine in which he was seen relapsing ideally into his character as an untrammeled human being, a bruiser at country-fairs, a sportsman on Scottish hills and rivers, a boon companion with Highlanders, a knight of free manners, on life and literature, from the point of view of an inspired king of the gypsies or from amid the upraisings conditions of a city orgy." Among these papers of riddles phantastical, the most famous were the series called the 'Noces Ambrosienses,' of which the first and second were published in 1825, as well as Wilson, was a contributor to Blackwood, but which, taken up in 1826 by Wilson for himself, after Lock-

thart's departure for London, were continued by him till 1836, when the death of the Etrick Shepherd, their principal correspondent, put a temporary stop to the publication of these 'Noces' that carried the name of 'Christopher North' over the world as the pseudonym of Wilson. They were followed by a series called 'Diss Boreales,' which extended from 1836 to 1846, but were less popular.

After the death of his wife, which took place about 1840 and left a profound sorrow in his heart, Wilson was much less active than he had till then been. He still figured as Christopher North in stray papers in 'Blackwood'; in 1842 he had published separately under that title 'Recreations of a Cynical Philosopher.' He died at Edinburgh, 1844, of paralysis, after a long illness. A volume of 'Noces Ambrosienses' was published posthumously in 1845, with a memoir by Sir Thomas Wilson, in which he is said to have written his most important contributions to the magazine; and still as 'The Professor' he was one of the lions of Edinburgh society and the idol of successive classes of students to whom he lectured his moral philosophy from the heads of a word onwards. He was, in 1824, at the height of his powers and reputation, and a man of great reach at the end of every eloquent period; but on the whole, the best of his career was over. Letterly, too, ill-health reduced his once abundant vigour. He continued in the discharge of his professional duties till 1852-53, when he retired from duties as a Professor of the University of Edinburgh, a year before a gold medal of $625. was obtained to him by government. He lived for a time in retirement at Lasswade, near Edinburgh; and died at Edinburgh on the 3rd of April 1864. In the follow-

Brougham. Having been restored to his rank in the army, he became a general in 1841, and held the post of governor and commander-in-chief of Gibraltar from 1848 till 1849. He died at Bow lofts, near Oxford, on the 9th of May, 1849. He was the author of a translation of General Regnier's 'Campaign in 1801 in the East and in Egypt,' and afterwards of a more correct original narrative of those events, published under the title of 'An Historical Account of the British Expedition to Egypt.' His other publications were 'An Enquiry into the Military Force of the British Empire' (1804), 'Campaigns in Poland with Remarks on the Russian Army' (1811), and a 'Sketch of the Military Politics of Russia,' in which he was severely criticized at the time of its appearance in the 'Quarterly Review.' Sir R. Wilson replied in an animated pamphlet.

WIN, PETER DE, was born at Stone, in Staffordshire, in 1784. He was apprenticed to Raphael Smith, the mezzotint engraver, and had for a fellow pupil, Fillion, the Academician, whose sister he afterwards married. Abandoning engraving, Mr. De Wint adopted painting in water-colours as his line of art; and was elected a member of the Society of Painters in Water-Colours, in 1810, six years after its foundation. For nearly forty years his pictures were among the leading attractions of the annual exhibitions of that society. He painted almost exclusively home scenery;—views in Kent, Lincolnshire, &c.; among the lakes and mountains, in Cumberland and Westmoreland; round the Thames, the Wy, and other rivers, corn-fields, hayfields, water-mills, and the like, being especial favourites with his pencil. His style was bold, broad, and vigorous, his colour treb; and in general effect his pictures represent some of the most striking pictures I have seen of England. But he was wasting in refinement, and in aiming at breadth of effect he was often negligent of details. His touch and texture were peculiar; but, allowing for an almost inevitable meanness, very agreeable and effective. Avoiding all the magic of the great water-colour painters for producing force and brilliancy, he continued to paint according to the method of the founders of the English school with washes of transparent colours only, but what he thus lost in power and variety he, to some extent, made up in the expression of his nature. He died on the 30th of June, 1840, in his sixty-sixth year.

Wordsworth, REV. CHRISTOPHER, D.D., was born June 9, 1774, at Cockermouth, Cumberland. He was the youngest son of Brownesworth Wordsworth, the younger brother of William Wordsworth the poet. He was educated at Hawkshead grammar-school, and at Trinity College, Cambridge, where he went in 1792, and took his degree of B.A. in 1796. He was elected Fellow of Trinity College, October, 1796, and was elected by his college to the living of a vicar in Westmoreland. In the same year he published 'Six Letters to Granville Sharp, Esq., respecting his Remarks on the Uses of the Definitive Article in the Greek Text of the New Testament.' 8vo, a volume which was praised by Bishop Horsey and Bishop Middleton, and procured him the patronage of Dr. Manners Sutton, Archbishop of Canterbury, who appointed him his domestic chaplain. He married October 6, 1804, Priscilla, daughter of Charles Lloyd, Esq., banker, of Birmingham, and in the same year was appointed to the rectory of Aby and Obey-with-Thorne in Norfolk, which vicarage he resigned in 1804. In 1805 he published 'Six Letters to Granville Sharp, Esq., respecting his Remarks, and a Second Letter to Lord Teignmouth.' In 1814 he published 'Sermons on various Occasions,' 3 vols. 8vo. He was appointed rector of St. Mary's, Lambeth, Surrey, and of Sundridge in Kent, April 10, 1816. Soon afterwards he served as chaplain to the House of Commons. On the 26th of July, 1820, he was installed Master of Trinity College, Cambridge. In the same year he exchanged the livings of Lambeth and Sundridge for the rectory of Buxted, with Uckfield, in Sussex. In 1824 and 1825 he published two elaborate volumes on the authorship of 'Ikeni Basiliké,' which he unhesitatingly ascribed to Charles I. The first volume, 'Reasons for supposing Ikeni Basiliké to be the work of Charles I., and answers,' 8vo; the second, 'King Charles the First the Author of Ikeni Basiliké further proved, in a Letter to his Grace the Archbishop of Canterbury, in Reply to the Accusation,' 8vo, 1822. These two works were received with much applause, and were succeeded by the present Master, Dr. Whewell. From that time he resided at Huxred, where he died February 8, 1846. He was buried in Buxted Churchyard. He had three sons. I. REV. John Wordsworth, born July 1, 1805, was Fellow of Trinity College, Cambridge, and died in 1839. II. Right Rev. Charles Wordsworth, M.A. and D.C.L. graduated at Christchurch, Oxford, was second master of Winchester College, and is now (1858) Bishop of the United Diocese of St. Andrew's, Dunkeld, and Dunblane, Scotland, to which he was consecrated in 1853. 3. Rev. Christopher Wordsworth, canon of Westminster, the author of many works, and among them Memoirs of his uncle William Wordsworth.

Wordsworth, William, was born at Cockermouth, Cumberland, in 1770. He was the youngest son of John Wordsworth, attorney-at-law, and law-agent to Sir James Lowther, afterwards Earl of Lonsdale, by Anne, only daughter of William Cockson, a mercer at Penrith. The Wordsworths came originally from Penistone, in Yorkshire, and on the marriage of their ancestor with an Englishwoman, and the name of Wordsworth's maternal grandmother was Crackanthorpe, of the Crackanthorpes of Westmoreland. The poet was therefore by pedigree a thorough North-of- England man. He had three brothers—Richard, who was the oldest, and John Wordsworth, attorney-at-law, and law-agent to Sir James Lowther, afterwards Earl of Lonsdale, by Anne, only daughter of William Cockson, a mercer at Penrith, and died in 1816; John, who was nearly three years his junior, and who became commander in the navy, and perished by shipwreck off Weymouth in 1800; and Christopher, the youngest, noticed above. [Wordsworth, W. A. C. C. S.]

He was the son of John Wordsworth, who was born in 1739, and the mother of his father died in 1778, when the poet was only eight years old; the father died in 1783, when the poet was but thirteen.

Till about the time of his mother's death, Wordsworth's eldest brother was at the school at Cockermouth and partly with his parents at Penrith, where he attended a dame's school; but about that time he was sent, with his elder brother, to a public school at Hawkhurst, in Lancashire, whither his two younger brothers were sent. His second brother, who remained, left very much at liberty to read what he chose, and to wander about in the neighbourhood. "I read," he says, "all Fielding's works, 'Don Quixote,' 'Gill Blas,' and any part of Swift that I liked; 'Gulliver's Travels' and the 'Tale of a Tub,' and 'An Essay on Man,' and the 'Iliad' and 'Odyssey.' He first began to write verses, as school-exercises, and to store his memory with observations of English rural nature. He became a fair Latin scholar, and was taught something of mathematics; but, upon the whole, the acquisitions possible at the school were not great. At the death of Wordsworth's father, which occurred while he was still at school, it was found that the principal part of his property consisted of a debt of 6000l. owing to his estate by Lord Lonsdale; a considerable part of what there was besides was expended in a curious experiment of which Wordsworth remained, when scrapped together, to complete the education of the children, under the guardianship of two uncles. By them Wordsworth was sent, in October, 1797, to St. John's Coll. Cambridge, to be educated at that college until January 1, 1801, when he quitted Cambridge altogether, having taken his B.A. degree. His recollections of his alma mater were by no means affectionate or reverential. He says:—

"I did not love.

Judging not perhaps, the timid course

And the much-studied essay, to

To see the river flow with ample range

And lower pace":—

and, in particular, he was repelled by the mechanical manner in which religious forms and exercises were gone through.

"Intellectually," says his nephew and biographer, "he and the university were not in full sympathy with each other. He had never been subject to restraint: his school-
days were days of freedom; and latterly, since the death of his parents, he was almost entirely his own master. In addition to this, his natural temperament was eager, impetuous, and impatient of control. At college, however, he read and thought much; he studied Italian; and he began to set himself a number of questions in order to gratify his passion for the open air and for scenes of natural beauty and grandeur; and one of these tours, made in the autumn of 1790, with a fellow-collegian, was a pedestrian tour through France and Switzerland, at the very time when the French Revolution was beginning. In 1791, after taking his degree, he spent some time in London, and made a pedestrian tour in North Wales; and in the autumn of that year he went over to France, where he spent fifteen months in all, partly in Paris, partly in Orleans, and-chiefly in Normandy, in the district of Sées. The king was deposed when I was at Blois: and the massacre of September took place when I was at Orleáns. Wordsworth was no mere indifferent spectator of the scenes of the Revolution. At this time of his life he was a vehemcnt republican in France against all the rest of the world. He had friends too among the revolutionists of the Girondist party, and so fully did he share their enthusiasm that he even entertained the intention of becoming a naturalised Frenchman, and throwing overboard the English ideas of criticism and the ornamental side of poetry. By this time he had begun to believe that what it chiefly wanted to ensure a glorious success was the activity of a few steady, virtuous, and lofty minds, such as he was conscious of possessing. Of this he was still more convinced after Robespierre began to exercise his influence on the public mind. He considered the ideas of activity as he himself says, that is to say, he would have been one of Robespierre's victims, and have died on the scaffold with some of his Girondist friends. Circumstances however fortunately obliged him to return to England towards the end of 1793, a little before the execution of the king. He took up his abode for the time in London; but his thoughts were still on the other side of the Channel, and he followed the farther course of the Revolution with intense interest, complicated by personal interest. He was soon, however, becoming wearied of what he had engaged in an enterprising enterprise. Much of the influence of this time, though greatly modified, remained with Wordsworth throughout his life.

From 1792 to 1795, Wordsworth lived in a desultory manner in London and at a part of England. He had been destined for the church, and his friends were much disappointed at his preferring what seemed to them an idle and sinless life. His religious, as well as his political, principles, at this time were not of a kind conformable to the society to which he was destined; and his abilities for making a living by his intellects, was his passion; and he had already conceived the possibility of a new kind of descriptive poetry, which should do justice to the infinite variety of natural appearances that had been unnoticed by the poets of any age or country. In the course of the year 1792, he had a visit from Scott, and the beginning of his friendship with that poet, is often given as the encouragement to Wordsworth to undertake a course of poetry. Scott, Wordsworth writes, informed him that he was about to publish a volume of poems of this kind in the heroic couplet; 'An Evening Walk, addressed to a Young Lady,' and 'Descriptive Sketches, taken during a pedestrian tour among the Alps.' It was the time of the rise of a new poetical spirit in England, and Grisley having just appeared in the field after Cowper, and the Scottish poets Burns being then in the full flush of his fame. New poets were also springing up; and one of these, Coleridge, thus describes the impression made on his mind by this volume: 'It was presented to me on the morning of the 18th of May, 1793, and as nearly as I can now remember, it is among the most important things that ever was published: 'During the last year of my residence at Cambridge, I became acquainted with Mr. Wordsworth's first publication, and seldom, if ever, was the emergence of an original poetical genius above the literary horizon more evidently announced.' Thibaud, however, did not, however, entertain the intention of continuing and for a while, Wordsworth's prospects were very uncertain. Having no independent means of livelihood, he contemplated entering the legal profession and supporting himself meanwhile as a political writer on the liberal side for the London newspapers. He even contemplated publishing 'Sentiments on a Discerning Generosity of a Young Friend, named Calvert, who, on his death in 1795, left him 900, expressly as a token of his admiration and of his wish that he would devote himself to poetry. This sum, judiciously managed, enabled Wordsworth to adopt a mediocrity between a life of study and one of travel. He cultivated various forms of intellectual and physical recreation at this time, and he exercised a wonderful influence over his spiritual and his physical, to live for some seven years, without any necessity on his part to undertake any employment incompatible with his freedom as a poet; and as it fortunately happened that, at the end of that time (1809), a sum of 8,600, was paid over to the family by the second Earl Lousdale in liquidation of the debt owing to their father by his predecessor, there was again a sufficiency of means for the poet's purposes.

In the autumn of 1796, Wordsworth and his sister settled at Racedown Lodge, near Crewkerne, in Dorsetshire; and here, living in a quiet and happy manner, he wrote his 'Salisbury Plain, or Guilt and Sorrow,' and began his tragedy of 'The Borderers,' neither of which was published till long after he had returned to London. In June 1797, Coleridge visited him, and paid his first visit to the Wordsworths; and 'for the sake of being near him when he had removed to Nether-Stowey in Somersetshire, we removed,' says Wordsworth, 'to Allfoxden, three miles from that place. This was in August 1797, and Coleridge, writes Wordsworth, 'was the result of the two poets the appearance in 1796 of the 'Lyric Ballads,' a small dodecimo volume, published by Mr. Cottle of Bristol, the first composition of which was the 'Ancient Mariner' of Coleridge, and the rest, to the number of twenty-five pieces, of which was also carried by Cottle, that was the first one of Cottle's, who has taken his 500 copies, the greater portion of which was remanufactured; and when Mr. Cottle shortly afterwards gave up business, and sold his copyrights to the Messrs. Longman of London, the copyright of this little volume was valued at £50, Mr. Cottle renewing it, before the end, also, by a subscription to Cottle's authors. Little affected by the indifference with which the volume had been received, or by the contemporaneous rejection of tragedies which they had respectively submitted to London theatre-proprietors, they were engaged in a new work. In 1798-9, they published in instalments from Grasmere, verse that made occasional excursions of business or pleasure. Thus in 1809 he made another tour in France; on his return from which he married Mary Hutchinson, whom he had known from his childhood. Wordsworth's sister still continued a member of the household, and the intellectual companion of William in all his labours. In 1803, the poet, his wife, and his sister, set out on a tour in Scotland, in the course of which they made the acquaintance of Scott, and gathered observations and impressions which served as future materials and subjects. Before their return, Wordsworth had written the lines that make the poet's eldest child, a son, named John, was born; and the poet's other children were all born either at Grasmere or at Allan Bank—a daughter, Dora, in 1804; a son, Thomas, in 1806; a second daughter, Catharine, in 1808; and the youngest, a daughter, Mary, in 1810. The period of Wordsworth's residence at Grasmere and Allan Bank (1799-1813) was the period of his memorable struggle against the critics, and of the slow and gradual recognition of his poetic genius. He was incessantly active, turning his observations and thoughts into poems, and he had projected and was occasionally laboring at his great philosophical poem in blank verse, of which 'The Prelude' and the 'Excursion' are the accomplished fragments. What he presented to Coleridge in the summer of 1806 was the unfinished manuscript of the poem. In 1808 appeared a second edition of the 'Lyric Ballads,' in two volumes, with numerous additions; and there were subsequent editions in 1809 and 1805. In 1807 appeared a distinct collection of pieces, entitled 'Poems in Two Volumes;' and in 1808 they entered into the 'Cumbrian Association' and the 'Invention of Cintra.' This last work was published contemporaneously with the first numbers of Coleridge's 'Friend,' to which Wordsworth contributed his 'Essay on Epitaphs.' In 1810 the poet wrote a portion of the letter-press for a volume entitled '楮Cornwall, Devon and Lancashire,' edited by Rev. Joseph Wilkinson—a fine mark of his interest in the lake scenery, and his desire to diffuse the love of natural beauty. It seems to have been Wordsworth's theory not only that the enjoyment of nature would have the beneficial effect on the minds of men in general, worthy of being systematically taken into account and reported to, but also, that it is part of the functions of the poet to minister this influence of nature, by permanently connecting himself with some one spot or district, so as to transfer its pecu-
lier facts and teachings into his poetry. Hence a greater fitness in the name ‘Lake Poets’ than was intended by those who invented it.

Wordsworth appeared professedly not only as a new poet, but also as the representative and champion of a new theory of poetry. In the volumes he had published up to this time he had not only exemplified his principles of composition in the poems themselves, but he had also propounded and illustrated those principles didactically in prefaces and dissertations. He held, with Coleridge, that the poet in the history of English Literature intervening between Milton's age and his own had been, with a few exceptions, a kind of interregnum in English poetry—a period during which, as Wordsworth said, 'the art of prosody declined as to themes and as to style; and what he claimed for himself and for those who were associated with him, was the merit of reviving the true notion and art of poetry. The following summary has been given of his views:—Poetry, and religious poetry, taking origin from emotion recollected in tranquillity; what the poet chiefly does, or ought to do, is to represent out of real life, scenes and passions of an affecting or exciting character. Now, men originally placed in such scenes or animated by such passions saw a nervous and lively passion, and as well, also, very few of them had employed nature herself; and the poet therefore in imitating such scenes and passions, will recall them more vividly in proportion as he can succeed in employing the same language. Only one consideration should operate to make him modify the natural methods of speaking the language of his own time; and that is, his own health; a poet, as a poet to give pleasure. All such words or expressions therefore as though natural in the original transaction of a passionate scene, would be unpleasant or disgusting in the poet's rebuke must be omitted. Purified added in accordance with his science, is an estimation of moving occurrence, whether in prose or in verse, would true poetry. But to secure still more perfectly their great end of giving pleasure, while they excite emotion, poets use the language of their subjects, to the metre and allusions, which had become a kind of property of the poetic corporation or guild, and which, though originally they might have arisen from genuine observation of nature, had by incessant repetition and attrition become mere lifeless artifices; while his imagination and powers of deduction at all resembling the language of real men and women under any circumstances, counting it rather the essence of their craft to use a certain conventional phraseology, called poetic diction, in which words were deformed out of their natural order, and the distortion regarded as metrical art.

These views naturally provoked opposition, as similar views had already done when urged by Bowles; and Wordsworth's poems, exemplifying these views, were either neglected or sneered at. Indeed, in 1811, one of his visionists he had selected, for many of his pieces, very simple subjects, and had written a language as close as possible to that of real life; and these pieces were fastened on by the adverse critics and held up to ridicule as childish, grotesque, &c. Thus began the great literary controversy as to Wordsworth's poetry—a controversy which lasted almost to the end of Wordsworth's life, though by that time his triumph was, on the whole, decisive, and his admirers included the best part of the literary world. His method was never at a loss for afflicting the appreciation of what he had already published, partly of the appearance of other poems, thrown out at intervals from his retreat among the Lakes, each making a new impression and some revealing the poet's powers dissolved, while his withering allusions were as subjects to the critics of the old school. In 1813 he took up his residence at Rydal Mount, not far from his former habitations; and here he remained till his death, allowing for occasional visits to London, a second tour in Scotland in 1814, a new continental tour in 1820, a tour in Holland and Belgium in 1823, in North Wales in 1824, on the Rhine in 1828, in Ireland in 1829, in Scotland again in 1833, in Italy in 1837, &c. Before his removal to Rydal Mount, his children Catharine and Caroline had died childless. In 1820, his brother Allan died. His poems were as yet no source of income to him; but just at the time of his removal to Rydal Mount, he was appointed, through Lord Lonsdale's influence, to the dispensation of stamps for the county of Westmoreland, a post which, with light duties and the advantage of permitting him to remain in the district of his affections, afforded him a little more than a hundred pounds a year. In 1814 he published his great poetic poem of ‘The Excursion.’ It had little commercial success and drew down the censure upon him more than before; including Jeffrey's famous verdict 'this will never do,' but at the same time it was more immediately popular; this, very shortly, by 'The Waggoner,' dedicated to Charles Lamb, and 'Sonnet on the River Duddon.' The poems had, most of them, been in manuscript long before they were published. In 1828 (by which time there had been new editions in favor of the previous editions) and 1839, Wordsworth's name was pronounced everywhere as that of a literary power of the highest order appeared Somnara and other Poems under the title of 'Mourning of a Tour on the Continent; several years afterward with the essays and his 1806 years. He had published his collected edition of his poems in seven volumes, re-arranging them in a new order on a peculiar principle of his own, and with new titles to the separate parts of his work. Several series of editions of his poems, which had never been published; and after Wordsworth's death appeared his autobiographical poem, 'The Prelude,' written in the early part of the century, and bringing down the narrative of his life till the period of his determination to become a poet after his first suicide, and the series of poems published under the title of 'Poems in Two Volumes' died, that in 1847. He was in D.C.L. of Oxford; in 1842 he had resigned his post of Distributor of Stamps, and in 1843 he was knighted and made Poet-Laureate. His wife and his sister, and two sons survived him. His only daughter Dora had married in 1841 Edward Quillinan, Esq., a gentleman who had been the army and the 1852 of the 20th century. They were the last to survive him. He had been married to a woman of genius in France, and for her he married for the health of Portugal and Spain, of her travel in which countries she published a journal; and after her return she died in 1847. The death of Wordsworth, in two volumes was published by his nephew Canon Wordsworth in 1851; and contains many letters, dictations, and conversations, illustrative of the occasions of his poems, of his character and habits generally, and of his progressive views of men and time. These letters were the result of his own composition and diligent observation of all that occurred at home abroad; and he expressed strong and decided views on great political events and movements of his time, such as war with Napoleon, Catholic Emancipation, the French Revolution of 1847, the Reform Bill, the Railway Mania, &c. His views on these subjects were generally Conservative; in contrast with those which he had held so strongly in life, and in some of his letters and conversations he alludes to this apparent change and gives the philosophy of it. In 1843 he had received from the Universities the title of 'Conservative' by publishing 'Two Addresses to the Freethinkers of Westmoreland.' He was during the last few or fifty years of his life a zealous and devout supporter of the Established Church of England. A lofty and severe man who, had not a strict moral manliness, but a sincerity and great horror of sin, was consecrated from first to last to the service of the great permanent, and the noble. His influence on the literature and especially on the poetry of Britain and America this century, has been immense, and is far yet to be exhausted.

and brother of Princess Dashkov. Semen Woronzow was for many years Russian ambassador to England, where he was first sent by the influence of Prince Potemkin, in 1792, to the British embassy till 1810, when, retiring from the service, on account of ill-health, he obtained permission from his government to remain in England, and resided in London as a private gentleman till his death in 1833, at the age of eighty-nine. His son WYATT, RICHARD, an eminent sculptor, was born in Oxford-street, London, on 16th May, 1755. Having chosen sculpture as his profession, he was placed in the pupil of Charles Ross, R.A.; and about the same time he entered the Royal Academy as a student. During the seven years which he served with Ross, he twice carried off medals at the Academy, and after leaving his master, he spent some time in the atelier of Boeio at Paris, and he completed his professional education under Canova, whose acquaintance he formed in London, and who kindly invited him to Rome, and offered him his advice and assistance in the prosecution of his studies. As a fellow-student, and the friendship here formed among the young students, who were ultimately to rank together as the first English sculptors in Rome, remained unbroken through life. With Canova Wyatt likewise retained the warmest friendship, in the death of the great Italian master. Wyatt went to Rome in 1821, and he made that city his permanent abode, only once making a brief visit to his native country in 1841. He died suddenly at Rome on the 29th of May, 1850.

Wyatt was a man of singularly gentle unsunsming temper, and quiet retiring habits. His whole life was spent in the diligent prosecution of his profession—at which he laboured often from dawn till near midnight. The number of his works is very great, and they are by no means inferior to many of his contemporaries. He was undeniably one of the first of his profession, and his works, combined with and especially his female figures, are beautifully modelled, always poised with grace and animation, and always present pleasing forms from whatever side they are viewed. His dripries too are invariably well cast, and he express TEXTURE. His anatomy is truly classical, and his treatment of the human form is as exact and true as it can be. As examples of his style may be mentioned his statues of 'A Nymph entering the Bath'—one of his most beautiful of his many versions of which, was that executed for Lord Charles Townshend, of the Bath; 'Shepherdess with kid'; 'idem with dog'; 'Olympia'; 'Ariadne'; 'Bacchus'; and 'Penelope,'—an exquisite statue executed for her Majesty; and his admirable groups of the 'Nymph Eucharis and Cupid'; 'ino and Bacchus'; 'Nymph of Diana taking a horn from a greyhound's foot;' and 'A Huntress with a Leveret and Greyhound'—his last work. He also produced many excellent portrait busts, some rilívi, and monumental sculpture. At the Great Exhibition of 1851, several of his works were exhibited, and the medal for sculpture was awarded to him on the recommendation of a number of the members of the Royal Academy, a bye-law of that institution rendering artists ineligible resident in England. Casts from several of Wyatt's work,—including most of those named above—are in the Crystal Palace at Sydenham.

WYON, WILLIAM, an engraver and designer of medals and coins, was born at Birmingham in 1795. The pursuits and associations of his family (of German descent) were peculiarly calculated to give direction to his mind and to foster whatever natural abilities he possessed. His grandfather, George Wyon, engraved the silver cup embroidered with a design of the assassination of Julius Caesar, which was presented by the city of London to Wilkes. His father, Peter Wyon, to whom, in 1803, he was apprenticed, was a die-sinker of reputation at Birmingham, and with him was associated William's uncle, Thomas, as partner, to whom young Wyon was much indebted. The earliest of his productions of which we find any marked notice were copies of the heads of Hercules and the left of the head of George IV. engraved for the Society of Arts, and was purchased by it for distribution as an agricultural prize. A second gold medal from the same body marked the appearance of Wyon's group—"Victory drawn by Tritons." A few years later he completed a figure of Antinous, which so delighted his father that he let it set in gold, and wore it constantly until his death. Wyon came to London in 1816, and won his way through a competition to the post of second engraver at the Mint. Sir Thomas Lawrence was the umpire, and the trial piece of the head of George IV. His prospects were now most fa- vorable, and his situation altogether agreeable to him—for the chief engraver, Thomas Wyon, was his friend and cousin.

G.
But unexpectedly the latter died, and Mr. Pritzruci was nominated in his place. The new engraver and his chief assistant could not agree. Pritzruci, a skilful artist, is said to have been indolent, and while reserving to himself the greater share of the honour and benefit, he left the greater amount of labour to Wyon. Under a new Master of the Mint these differences were compromised by an arrangement, which left Pritzruci nominally chief engraver until his death, but gave half his salary to Wyon and the other half to Pritzruci. On the death of the younger artist these occurrences, further than to observe that the younger man found an enthusiastic champion who issued a memoir of his life, and a list of his works, then exceeding two hundred in number. The Royal Academy marked its opinion of this controversy, and of Wyon’s own merits, by electing him in 1835, an Associate, and in 1838 an Academician, the first of his department who had ever obtained these honours.

Wyon’s works may be divided into coins—pattern pieces of coins not supposed to be issued seals. His coins include those of the later years of the reign of George IV., all those of William IV., and all those of her present Majesty which appeared in Wyon’s lifetime. He followed Chantrey’s models in the coins of both the kings, but was his own designer in the coins of Victoria. The pattern pieces include one of ten pounds for William IV., and one of five pounds (among several others) for the present Queen, which bore a figure of Una on the reverse. These pattern pieces did not become coins through the influence of the body, who, at that time, under the title of moneymen, were the privileged coiners of the country, and who knowing that increased expense would be necessary, took care of their profits, and did not trouble themselves about Wyon’s disappointment or the interest of the public in the increase of objects, and were produced for many different and admirable objects. There are war medals for the Peninsular victories, for Trafalgar, for Jellalabad and Cabul; scientific medals for the Royal Society, Royal and London Institutions, Geographical, and similar societies, native and foreign artistic medals, as for the Royal Academy and Art Union educational, as for Harrow, a gift by Sir Robert Peel; an testimonial, as in the case of the Brodie medal, which bore a third of the man in the same house; it was struck. These medals have for their obverse heads taken from the antique, a few modern, and in some cases, then living personages; and the author had generally aimed, as a matter of course, at his own characteristic fitness being the pure strain of the prehistoric age, the accompanying circumstances, thus Cholmondeley selected the Peel-Harvey medal, while heads of Lord Bacon, Sir Isaac Newton, Dr. Wallis, and Sir Francis Chantrey, were respectively and appropriately connected with the medals of the Royal Institution, the University of Glasgow, the Geological Society, and the Art Union. Many—and among them some of the best—of the reverses were from his own designs; while for others Wyon was indebted to Flaxman, for whom he had an enthusiastic veneration, Howard, and Stockard, who contributed the reverse, to the medal of court. Wyon’s increasing eminence was shown in the various commissions he received from foreign countries; we may especially mention his engagement for a series of Portuguese coins.

The characteristics of Wyon are the combination of two (often opposing) qualities, strength and delicacy, with the indispensable merit of likeness in his portraits; taken for all in all, we have had no such medal engraver since the days of Simon, the artist who shed so much lustre on this department in the days of the Commonwealth. Wyon died at Brighton, October 29, 1851, in his fifty-seventh year, a son, Leonard, who having aided him in his lifetime, inherited much of his skill at his death. To the latter we owe the well-known medal of Wordsworth; and his name is connected with that of his countryman, the Great Exhibition; and is thus gratifyingly associated in art as in blood with the subject of our present notice, whose latest works were in commemoration of that same assemblage of the world’s industrial and artistic fruits.

Y

YARRELL, WILLIAM, a celebrated British naturalist, was born in Duke-street, St. James’s, Westminster, in June, 1784. His father was a newspaper agent, and to his business his son succeeded, and continued in it till nearly the close of his life. When young he was fond of field-sports; but was not only the first shot, but the first angler of his day. The accurate habit induced by his superiority in these sports, was the prevailing character of his mind. He was not only the first shot in London, but for many years the first sporting authority upon all that had to do with the habits, laws, and manner of keeping of British birds. It was the same with fish. Not satisfied with obtaining his prey, he examined it, preserved it, and described it, and thus became a naturalist. At the age of forty he became a Fellow of the Linnaean Society, and from this time he gave up the gun and rod for the pen. From 1825 to the year of his death, 1856, he became a constant contributor to the Transactions of the Linnaean Society, and the various Journals devoted to natural history literature. His earliest papers were devoted to birds, as the following titles of some of his first scientific contributions show:—On the Change in the Plumage of some Hen-Pheasants (Philosophical Transactions, 117); On the Occurrence of some rare British Birds (Zool. Journal, II.); On the shall horned appendage to the eye, mandible in very young chickens (Ibid.); On the Anatomy of Birds of Prey (Zool. Journal, III.); On the Structure of the Beak and its Muscles in the Crosebill (Zool. Journal, IV.). He was one of the first members of the Zoological Society, and contributed not a few to the embellishment of the society and of the Cambridge University. In the first volume of papers published by the Society, Mr. Yarrell contributed no less than seventeen. They exhibit a wide and accurate knowledge of the forms not only of birds but of fishes and mammals. In these papers his conclusions are very sound, and they are very accurate. This is the more remarkable, as Mr. Yarrell had not the benefit of a medical education nor any further means of instruction than those supplied by his own industry. It was in these earlier papers that he demonstrated the true nature of White Ball, and showed that this pet morsel of the London epicure is a true species of fish, and not the young of the Shad, the Herring, or any other species of fish, as had been supposed up to his time. He did, however, consider that this British zoology, many of his papers being devoted to foreign animals, as the following:—On the Anatomy of the Lesser American Flying Squirrel; On the Woolly and Hairy Penguinea of Dr. Latham; On the Traches of the Stanhope Crab; and subjects of his research work. In this case the animals dying in the menagerie of the Zoological Society in Regent’s Park. He was always an active fellow of the Society, and one of its vice-presidents at the time of his death. He took a deep interest in the progress and development of the Gardens, as well as in the diffusion amongst the people of a taste for his favourite science. His various papers, amounting to upwards of seventy, the names of which are given in the ‘Zoological Bibliography of the Bay Society,’ prove him for the two great works of his life, the histories of British Birds and British Fishes. The ‘History of British Fishes’ appeared in two vols. 8vo, in 1836. It contained original descriptions, with an account of the habits, and a wood-engraving of every British fish. It was in every way an admirable work, containing accounts of several new fishes, with such descriptions as enabled the naturalist to distinguish them, whilst they were rendered by the agreeable style in which they were written attractive to the dullest of anglers. A second edition appeared in 1839. The ‘History of British Birds’ appeared in 1843. It was on the same plan as that of the fishes. The illustrations in wood were accurate and beautiful, and highly creditable to the enterprise and taste of his publisher Mr. Van Voorst. No work on the subject since Mr. Yarrell’s has become so popular. In many of his details, especially his picturesque tail-pieces, it imitated his great predecessor, but in point of accuracy of description and the homely
truefulness of his account of the habits of birds Mr. Yarrell had made. At the time of his death Mr. Yarrell was treasurer of the Linnean Society, and had been elected vice-president during the presidency of Robert Brown. Although one of his earliest papers was published in the 'Philosophical Transactions,' Mr. Yarrell was never made a Fellow of the Royal Society. He was continually proposed, but some unobjectionable objections having been made to his admission he withdrew his certificate, and although in the latter part of his life, the Royal Society would have gladly admitted him amongst its fellows, and his certificate was given the 1st of December, 1836. He was interested at Bayford, Herts.

YEAST, a substance found on the surface of fermenting liquors, and when removed capable of producing fermentation in other liquids susceptible of this action. On placing Yeast under the microscope it presents a number of cells imersed in a mass of amorphous matter. The cells are sometimes single, and at other times several are united together in a kind of chain. These cells are supposed to partake of a fungoid character, and they have been called the ferment-cells, and are supposed to have been constituted for the reception of this organism, under the name of Saccharomyces Cerevisiae.

This plant has been supposed to be the active cause of fermentation, and the carbonic acid given off during that process. The phenomena of the fermentation are, for the most part, observable on the plant. This seems to be a misinterpretation of the phenomena, as the plant is probably the result of the carbonic acid given off during the process of fermentation rather than the cause of it. These ferment-cells originate in liquids, independently of other cells, and are truly instances of the formation of cells in a free fluid. He observes, however, that they have no power of reproducing other cells. The whole subject of the nature of the cell has been much discussed by chemists, botanists, and philosophers, and their development, as well as the phenomena of fermentation in general, require further elucidation. (Schleiden, Principles of Scientific Botany; Microscopic Dictionary, articles 'Fermentation,' 'Torula,' 'Yeast.')

YELLOW COPPER ORE. [Mineralogy, 8.1.] YOUNG, THOMAS, M.D., was born June 13, 1773, at Millerton, in Somersethshire. He was the eldest of ten children of Thomas and Sarah Young, who were both Quakers. He was sent to school at Stapleton, near Bristol, and in 1782 was sent to the school of Mr. Thompson, at Compton in Dorsetshire, where he remained nearly four years. During this period he studied, besides Latin and Greek, the French, Italian, and several other languages. He was then sent back to his native city, where he devoted himself almost entirely to the study of Hebrew, and to the practice of turning and telescope-making, which he had been taught by a usher of Compton school. In 1787 he accepted, in conjunction with Mr. Hodgkin, an engagement as private tutor to Hudson Gurney, grandson of Mr. David Barclay, of Youngsberg, near Ware, in Hertfordshire. There he remained till 1792, devoting his leisure hours to the prosecution of his studies in Greek, Latin, and modern languages, Oriental and Hebrew, algebra, fluxions, natural philosophy, and the 'Principia' and 'Optics' of Newton. Mr. Hodgkin in 1793 published 'Calligraphia Graeca,' which he dedicated to Young, who had suggested the work, and furnished the writing.

In 1794 Young moved to London, in order to study medicine by the advice and on the invitation of Dr. Brocklesby, an eminent physician, who was his maternal uncle. Young was by introduction introduced to Mr. Burke, Sir Joshua Reynolds, and other literary and scientific men, and he became connected with the Royal Institution, Ballie, Cruikshank, and John Hunter. In the autumn of 1793 he entered himself a pupil at St. Bartholomew's Hospital, and in October 1794 proceeded to Edinburgh, still further to prosecute his medical studies. There he attended the lectures of Dr. Edkins, and was induced to give up some of the external characteristics of the Quakers; but the change of habits and associations in a short time led to a total and permanent separation from them. He mixed largely in society, began the study of music, and took lessons on the flute, and also private lessons in dancing, and frequently attended the performances at the theatre. In the summer of 1795 he made a tour to the Highlands of Scotland.

In October 1795 he left London, in order to make a tour on the Continent. He took a doctor's degree at the university of Gottingen, and prosecuted his studies there during nine months. In May 1796 he made a tour to the Alps, and ascended some of the deepest mines. After leaving Gottingen, he visited Gotha, Erfurt, Weimar, Jenne, Leipzig, Dresden, and Berlin, and returned to England in February 1797.

Almost immediately on his return home Young was admitted a Fellow Commoner of Emmanuel College, Cambridge. Dr. Brocklesby died December 13, 1797. He had fostered the promising talents of his nephew, had prepared for the latter his general and professional education, and now left him but about 10,000l. and his house in London, with furniture, library, and a choice collection of pictures, mostly selected by Sir Joshua Reynolds. After this, Young resided sometimes at Cambridge, and sometimes at Bath, Wortington, and elsewhere.

Having, in 1799, completed his last term of residence at Cambridge, in 1800 he settled in London, and commenced the profession of medicine. His practice, however, was rather less extensive than were his studies. It was not till 1805 that he gave to the world, at his own time to his favourite literary and scientific pursuits. Several years were then required to elapse between the date of admission of a student at Cambridge and the granting of his degree in medicine, so that Young did not obtain his medical degree till 1805. He was elected a fellow of the Royal Society in 1807. Before the latter date he had written his memoir, 'Outlines and Experiments respecting Sound and Light,' which was read before the Royal Society, and printed in their 'Transactions.' Other papers on 'Optics and Light and Colours' followed, which the Council of the Royal Society selected for the Bakerian lectures.

In 1801 he accepted the office of Professor of Natural Philosophy at the Royal Institution, which had been founded, as he understood, for the promotion and establishment of the higher branches of science in this kingdom. Young was in 1810 he was appointed Foreign Secretary to the Royal Society, an office which he held during the remainder of his life, and for which he was well qualified by his knowledge of the principal languages of Europe. He married July 14, 1804. After fulfilling for two years the duties of Professor of Natural Philosophy to the Royal Institution he resigned the appointment.

During the time he was connected with the Royal Institution he delivered sixty lectures, which form the substance of his great work, which was published in 1807, and entitled 'A Course of Lectures on Natural Philosophy and Mechanical Arts.' This work contains also his optical and other memoirs and a clased catalogue of all his publications. A new edition was published in 1845, 'with References and Notes, by the Rev. P. Kelland, M.A., F.R.S., &c., illustrated by numerous Engravings on Copper,' 8vo.

These lectures embody a complete system of natural and mechanical philosophy, drawn from original sources; and are distinguished not only by extent of learning and accuracy of statement, but by the beauty and originality of the theoretical principles. One of these is the principle of interference, which was first suggested by Young, and the name was very unfavourable. The novel theory of undulation especially was attacked in the 'Edinburgh Review,' and Dr. Young wrote a pamphlet in reply, of which only one copy is known. He was also assailed on account of his French philosophy, Fresnel, who entertained him similar to his own on the nature of light. The undulatory theory is now generally received in place of the molecular or emanatory theory. Among the other difficult matters of investigation in which Dr. Young was engaged, was his study of Egyptian Hieroglyphics, in which he first proceeded Champollion. [Champollion, J. F.]

In 1809 and 1810 Dr. Young delivered at the Middlesex Hospital a series of lectures on the elements of medical science and practice. In January 1811 he was placed one

5 G 2
of the physicians of St. George's Hospital, a situation which he retained for the remainder of his life. His practice there, as elsewhere, is stated to have been eminently successful. In 1815 he published 'An Introduction to Medical Literature, including a System of Practical Noso logic, intended as a Guide to Students and an Assistant to Practitioners,' 8 vols. In 1816 he received the degree of Doctor of Medicine in the University of Mos cou for ascertaining the length of the second's pendulum, for com paring the French and English standards with each other, and for establishing in the British empire a more uniform system of weights and measures. He drew up the three regularly ordered volumes of 'The Description of Russia' in 1819. In 1821 he was appointed secretary to the Board of Longitude, and on the dissolution of that body he became sole conductor of the 'Nautical Almanac.'

Dr. Young at various times contributed eighteen articles to the 'Quarterly Review,' of which nine were on scientific subjects—the rest on medicine, languages, and criticism. Between 1816 and 1823 he wrote sixty-three articles for the 'Supplement to the Encyclopaedia Britannica,' of which forty-six were biographical. In 1821 he made a short tour in Italy in company with his wife. In August 1827 he was elected a Fellow of the Royal Society.

ZAGOSKIN, MIKHAIL NIKOLAEVICH, a Russian dramatist and novelist, was descended from a Tartar family, and was born on the 14th of July (O.S., 1792), at the village of Ramazay, in the government of Penza. He remained in his native village till the age of fourteen, receiving but a slender education, and learning no language but Russian, but he early showed a genius for literature, and could understand, and compounding a tale at the age of eleven. At fourteen he was sent to St. Petersburg as a clerk in a government office, and continued in that kind of employment till the outbreak of the war of 1812, when he became a private soldier in the Petersburg Dragoon Regiments. He took part in the campaign against the French, was wounded at the battle of Pokotuk, and before the close of the war rose to be adjutant to General Lewis at the siege of Danzig. By this time he had acquired some knowledge of French and German, his long dormant literary tastes revived, and not long after he had taken leave of a military life— he set up anonymously a comedy, called 'Prokaznik' or 'The Wag,' to Prince Shakovsky [Shakhovsky, S. 2], director of the St. Petersburg theatre, who had himself just returned to the duties of management, from the command of a regiment of Cossacks. The reply was so unexpectedly favourable, that Zagoskin on once made himself known, and Shakovsky even procured for him a post connected with the theatre, and another as an inspector of the Imperial 'Free and Imperial Literature,' where it was told that for his services in arranging to the books and catalogue the Russian one, he received the Order of St. Anne of the third class. This was the commencement of his career as a dramatist, which he pursued first at St. Petersburg, and after 1820 at Moscow, to which city he was transferred as director of the theatre. He wrote altogether seventeen original comedies, some in verse and some in prose, several of which met with distinguished success, and none failed except the last. The best known of his plays are 'The Courageous Man of the Metropolis, ' 'Bobotev, the Second, or the Metropolitan in the Country,' 'A Romance on the Highroad,' and 'The Journey Abroad.' It is worthy of remark that till beyond his thirtieth year Zagoskin had not written a line of verse, his ear had been insensible to the rhythm of sound and measure, and that in 1821, on some of his friends laughing at him for pretending to give his opinion on poetry when he laboured under this deficiency, he was piqued into saying that he would write he could write as much as he could after all, and setting doggedly to work, and making progress at the rate of four lines a day, correcting the metr on his fingers, he produced some verses that were not only rhythmically correct, but remarkable for their grace and freedom. After this he frequently wrote in verse, but deserted the operation; and when he determined to write a romance in imitation of Walter Scott, one chief inducement was to enjoy a double freedom from the trammels of rhyme and the rules of the drama. The tale he produced, 'Yuri Miloslavsky ili Russky roman v 1612 Godu' (George Miloslavsky, or the Russians in 1612,) 3 vols., Moscow, 1827, described the state of Russia at the time that it was nearly conquered by the Poles. The success it met with was prodigious. 'The appearance of this romance,' says Zagoskin's biographer, 'at that time, was a signal step in the literary and social career of Zagoskin. The enthusiasm was unbounded and unanimous; few indeed were there who did not fully share it. The public of both the capitals, and after them, or rather with them, the public of all the provincial towns, gave it a cordial reception. The Czar to whom 'Miloslavsky' is read by all Russia that can read, and not without cause; the Russian mind and soul, and even the Russian way of speaking, were for the first time represented in Russia in this romance. An English translation of it appeared in London in 1834 under the title of 'The Young Muscovite, or the Poles in Russia, edited by Captain Frederic Chamier, R.N.,' and was said in the preface to be 'edited from a manuscript translation of the book made into English by a Russian lady of high rank and two amiable daughters,' to which the editors, for it appears that there were more than one, took the liberty of adding 'an underplot by which the characters of the chief actors are further developed. Although of course these altera tions do nothing to enhance the value of the book as a picture of Russian life in those characteristic ages, but as correct, they are not so extensive as to spoil it. Speaking of it from a full perusal of the original, we should say that 'Georgy Miloslavsky' was an amusing third-rate tale, rather unequal in its progress, and falling off sadly toward the end. Zagoskin was hailed as the Russian Walter Scott. For his next tale 'Rostavlev,' a story of Russia in 1812, in which he introduced some of his own adventures, there was an unheard-of competition in the Russian publishing world, for which purpose the story of the hero of the novel is a real poet for the copyright, but it was far from attaining the success of its predecessor. Zagoskin went on writing novels and romances, and in general founding a play on each after it appeared; but the merit and popularity of his works went steadily on increasing, and the productions of 1827 were considered to rival 'Yuri Miloslavsky,' or even 'Rostavlev.' He continued to reside at Moscow, where he enjoyed the additional appointment of director of the Armoury of the Kremlin, and was a well-known and popular member of the best society, which his never-failing good humour and disposition to Merriment qualified him both to enliven and to enjoy. Almost his only work besides his plays and novels was a collection of essays entitled 'Moskva i Moskvochki' (Moscow and the Moscovites,) which ran to three or four volumes, originating in gout, which he combated by homoeopathy, he suddenly expired at Moscow on the 23rd of June (O.S.)
1839. Soon after his death a life of him by Aksakov appeared in the 'Moskвитянin,' from which the foregoing particulars have chiefly been taken. His best works have an interest both to the native and foreigner from the purely Russian tone of their language and spirit, as indeed in every country the most popular national romance is a valuable clue to the key of national character.

ZAHRTMANN, VICE-ADMIRAL CHRISTIAN CHRISTOPHER, Hydrographer to the Danish Admiralty, entered the naval service of his country as a cadet in the year 1805, and afterwards rose to be a lieutenan. He has been undertaking many voyages, among which the war which terminated in 1815; acquiring the character of being one of the most able and accomplished officers of the Danish navy. At the general peace he betook himself entirely to geodetical and hydrographical work, and administration. Professor Schoumaker in the measurement of the Danish coast of the meridian. After a cruise to the West Indies, during which he made a chart of a portion of their seas, and set up an observatory on the island of St. Thomas, he was appointed Admiralty to Admiral Loverborn as director of the Hydrographick Office at Copenhagen. In this capacity, notwithstanding much prejudice respecting the publication of documents, he brought the labours of his department in an available form before the world, and with the highest degree of success. He has become so important to the navigators of all nations, on which his fame rests, as the charts of the coast of Denmark, with accurate soundings between the numerous islands, accompanied by determinations of the currents and trigonometrical reductions of the coast. His 'Chart of the Island of Iceland,' published in 1843, was indeed the greatest boon to all seamen, and to those of Britain in particular; whilst the 'Dancke Lods' (Danish Pilot), which is a complete description of all the seas surrounding this island. It has been translated, under the direction of Admiral Sir Francis Beaufort, F.R.S., late Hydrographer to the British Admiralty, into both the English and French languages.

He was also master-general of the naval ordnance of the Danish navy, had two maizes, a meteor bureau of Copenhagen, and a chamberlain of his sovereign, as well as a knight grand cross of the order of Dannebrog and Dannebrogsman, and a knight of four foreign orders, Russian, Prussian, French, and Greek.

He was an honorary member of the Royal Geological Society of London, and communicated to that Society, in 1830, shortly after its foundation, an account of Danish discoveries on the East Coast of Greenland in the preceding year. The paper, which was read at the meeting of the Geographical Society of Paris, appears in the first volume of the Journal of the former Society. In the same work, vol. iv., is an elaborate paper by him entitled 'Remarks on the Viewers to the Northern Hemisphere, according to the Zeni of Venice;' in which, communicated to the society in 1835, he arrives at the conclusion that those voyages, at least in the main points, are mere fabrications.

ZARIBNIS. [STURMILDE.]

ZARAGOZA. [SIRAGOMA.]

ZEALAND, NEW, a British colony in the Pacific Ocean and in the southern hemisphere, consists principally of two large islands, separated from each other by a wide strait called the Strait of Chatham, which is situated south of the two others, besides several islands, or rather islets, scattered along the shores. The more northern of the two large islands is called by the natives Te Ika a Maui, "The Fish of Maui," from a legend of its having been formed by a fish which opened the strait. The more southerly island is New Ulster, but is generally called North Island. The native name of the other large island is Te Waki Pounamu, "The Place of Pounamu," that is, of jade, used by the natives in forming their instruments of war. This island has been named New Zealand, but is generally called Middle Island. The small island has been named New Leinster, but is mostly called South Island, or Stewart Island. The islands lie between 34° 25' and 47° 20' S. lat., 168° and 178° 36' E. long. The two large islands are about equal length, and the entire length of the two is about 1000 miles. The width varies from a few miles to 300 miles. Stewart Island is about 60 miles in length and 60 in width. They are about 1200 miles eastward from Australia. The European population, according to the census taken in 1851, was 26,856, of whom 14,996 were males, and 11,860 females. The European population is now estimated at 40,000. The native population is estimated at from 80,000 to 100,000, of whom by far the largest number are inhabitants of North Island.

The British government in 1851 purchased the claims of the New Zealand Company for $266,370, to be paid out of the sale of waste lands in New Zealand. In the same year, by an Act of the British parliament (15 & 16 Vict. c. 72), a constitution was granted to the colony, the legislative power being vested in a Legislative Council and a House of Representatives. The seat of government is at Auckland. The colony is now divided into six provinces—Auckland, Wellington, and New Plymouth, in North Island; Nelson, Canterbury, and Otago (or Orokai) in Middle Island. Each district is placed under the management of a Superintendent and Provincial Council.

The colony has now four bishoprics—the bishopric of New Zealand, created in 1841, the bishopric of Christchurch, created in 1851, the bishopric of Wellington, created in 1857, and the bishopric of Auckland, created in 1858.

In 1849 the revenue was 48,384l.; in 1850 it was 57,745l.; it is now (1858) about 200,000l., the customs' duties amounting to 100,000l., and the land sales 80,000l. to 100,000l.

The greater part of the commerce of New Zealand is inter-colonial, but in 1858 the imports into Great Britain amounted to 100,000l., and the exports from Great Britain to New Zealand in the following year, were valued at 300,000l.

The principal staple is wool, sheep varying in 1841, 487 bales were imported from New Zealand into Great Britain, but in 1857 the import amounted to 3825 bales. Wheat is exported in large quantities to Australia, and there is sent to England, and there is sent to England, New Zealand. The mean annual temperature at Auckland is 58-43° Fahr., at London is 50-35°, at Naples is 61-49°, at Naples the mean temperature of the hottest month (January) is 79° Fahr., at Wellington it is 51° Fahr.; at London the mean temperature of the hottest month is 64°, and of the coldest month 37°. Lithium is known of the minerology of New Zealand. In October 1852 gold was discovered at Coronandel, about 40 miles E. from Auckland, on the peninsula forming the eastern side of the Gulf of Hauraki, between the harbours of Waihau on the western side and Mercury Bay on the eastern side. Gold has since been discovered in Nelson Province, and diggers are at work there. The chief export is wool, sheep and cattle being very large. Specimens of quartz-rock have been found exceedingly rich in gold. Copper has been found and wrought to some extent, but no lead or silver. Both islands contain coal, which is found at the surface, but mining for it has not yet been attempted.

The chief towns and villages in the colony of New Zealand are the following:

Auckland, the seat of the government of the colony, is built on the southern shores of the harbour of Waitemata, and is the southern port of New Zealand. It has an efficient depth for vessels of considerable burden. The town stands on cliffs of sandstone of moderate elevation, backed by rising ground. Several volcanic cones rise in its immediate neighbourhood, at the base of which are hard stones, grit for gravel roads, and easily worked; the sandstone of the cliffs, though soft, harder by exposure to the air, and is also a good building material. Some of the caves that occur in the cliffs have been used by the natives as places of sepulture, and the bottoms are covered with
human bones. The houses in the town are mostly of wood. The town is situated in a part of the island where the soil, though light, is fertile, and easily cultivated, and it has easy communication with all the countries both to the north and to the south. Many of the English, who settled on the island before the foundation of the colony, reside in the harbours marked of Auckland and Nelson, and small coasting vessels visit Auckland. Around Auckland are four pensioner-villages for discharged soldiers. Auckland was incorporated as a borough on July 29th, 1851, the district by which it is formed extending 16 miles in length, and 2 miles in breadth. It is divided into four wards, of which three are in the town itself. The Tamaki Creek intersects the borough, is navigable for boats, and is made available for the commerce of the district. The borough is governed by a mayor, aldermen, and a council, the latter consisting of twelve members appointed by the Governor. 

St. Paul's church, a handsome building; two sets of barracks built of soperi; a public hospital; a market-house; a native botelery; public washing, bathing, and drying grounds; several churches; and a bank. There are also several bridges, wharfs, and landing-places. The governor's residence and the bishop's are closely adjacent, and are about four miles from the town, on the banks of the Tamaki, is St. John's College. There is a church at each of the pensioner-villages. The population of Auckland in 1849 was about 4000; in the district in 1851 there were 8840, of whom 4921 were males, and 3919 females. The flag-staff of the barracks is in 51° 51'. 27°. 8 lat., 174° 42°. 10 E. long.

Wellington, the principal settlement of the New Zealand Company, founded in 1840, is on the shores of Port Nichol- son, in the island of New Ulster, but for governmental purposes the town and the whole of the district are comprised in the province of New Munster. Port Nicholson lies about 47° 30' North latitude, 175° 20' West of Greenwich. It is surrounded by mountains, except at the alluvial tract through which the river Hutt, or Eiritong, reaches the sea. These mountains rise abruptly from the water's edge, except in the most south-western corner of the harbour, where a strip of flat land extends for about a mile broad and two miles long, the soil of which is composed of sand, shells, shingle, and vegetable earth. On this flat ground, which surrounds that portion of Port Nicholson called Lambton Harbour, the town of Wellington has been built. It extends about three miles in the form of a semicircle round the harbour. The flat ground not being considered sufficient for the town, the hills south of it were included. As these hills are generally too steep to build on, only the most convenient parts were selected for that purpose, and thus the most distant points of the town are nearly four miles from the harbour. In 1848 there were 325 houses, of which 46 were of brick or stone, 303 of wood, and 171 of clay and wood, or other materials. However, the government has attempted to construct roads since, near the wharfs and jetties, which have been built so that vessels of 70 tons can unload alongside of them. There are two churches, and an Episcopal chapel, a Presbyterian chapel, five Wesleyan chapels, three other Dissenting chapels, and one Roman Catholic chapel, with a Roman Catholic bishop; there are also an hospital, a bank, a savings bank, a mechanics institute, a horticultural society, a custom-house, an exchange, a jail, two sets of barracks, and the residence of the lieutenant-governor. There are also various other kinds. Most of the public buildings are of wood only. The population of the district in 1851 was 5722, of whom 3133 were males and 2589 females. The town is well supplied with water by streams which run parallel with the coast and to the sea. Every public-house is compelled by the terms of its licence to keep burning; the streets are not paved, but excellent roads have been made in several directions along the coast to the valley of the Hutt, and towards that of Wairarapa. Two railroads have been constructed in the district, and all communications in the town, every public-house is compelled by the terms of its licence to keep burning; the streets are not paved, but excellent roads have been made in several directions along the coast to the valley of the Hutt, and towards that of Wairarapa. Two railroads have been constructed in the district, and all communications in the town are well kept. The passage by sea from 80 to 100 miles have been already formed, and a communication by land has been opened with Canterbury, a direct distance of about 170 miles, to Lyttelton. Coal exists in great abundance in the vicinity; one seam at Nelson and one at Waiapu are 20 feet thick, and contain 1000 tons of inferior coal each. In 1852 a new seam of superior quality was discovered by a landship at South Wanganui, at the north-west corner of the island, about 60 miles from Nelson in a direct line by land, but easily accessible by sea. Copper is also found near the Mountains, and a quantity is worked on the south side of the river, near the sea. The town of Wellington, situated between two small streams, the Huttoki and the Huri, near their entrance into the sea, on the northern side of the peninsula of which Cape Egmont is the western termination, and in the midst of which stands
the extinct volcano of Mount Egmont. There is no harbour properly so called, as the rivers are not navigable, and the mouths are small, nor is the roadstead a secure one. But this is the only drawback, for the country around has been called the garden of New Zealand. The land is so dry and so level that good roads are made with but little trouble, and the soil is the most fertile of any yet cultivated in New Zealand. The settlement was founded in 1841. In 1861 there were 45,425 males and 45,426 females. The town fronts the sea about half-a-mile from the beach, lying scattered on the slope of a hill, and contains two churches, one of them, a Wesleyan chapel also of stone, two other Dissenting chapels; a jail, schools, and several inns. There is a brewery and three flour-mills. Several bridges have been formed over the various small streams that descend from the sides of Mount Egmont and traverse the country. Iron and coal exist in the neighbourhing islands. Coal is found in abundance near the Wakanui River, about 50 miles N. from New Plymouth. Otago, in New Munster, is the district in which a settlement has been made by members of the Free Church of Scotland. It is towards the southern end of the island, on the eastern last. That town which lies called Dunedin is the Mounexuels River, which has been renamed the Clutha. The harbour formed by the mouth of the river is an excellent one; it is 13 miles long, and averages 2 miles in width; but the channel had difficulties which have been guarded against. It was opened by the late Mr. Hope and is now navigable. The settlement was made early in 1849; in 1851 the population was 1,740, of whom 994 were males and 746 females. The chief town, Dunedin, stands at the head of the harbour, and another has been formed near to the mouth of the river. Port Chalmers are 1,7° 46' S. lat., 170° 43' E. There was in 1848 only one place of worship, a Free Church chapel; but in 1850 the number of adherents to that doctrine barely reached a majority. The Clutha is a fine river, and, though it is free from a bar and consequent surf at its mouth, is said to be navigable for 60 miles for vessels of considerable burden. Coal is found at Coal Point, about 10 miles N. from the mouth of the Clutha, and at a spot within a quarter of a mile of the left bank. The珍惜 also been found in other places. A kind of green serpentine or jade is found here. Otaki is an exquisitely native village on the western shore of Cook Strait, about 50 miles N.W. from Wellington, and was the village where the islanders' last church missionary mission have taken much interest in this village, and not without success. Mr. Tyrone Power ('Sketches in New Zealand') describes it in 1848 as consisting of 60 houses neatly built, in the midst of well-frequented gardens. The houses consist of stone, or in some cases of bricks, in the number of pigs, cattle, and horses feeding about. The houses are of Maori architecture, with English doors, windows, &c. Mr. Power adds, that several of the chiefs kept 'a large number of hogs and fowls.' It is supposed that one of them taking an English officer to cash a cheque for him, having immediate occasion for money, which was done, and the cheque duly honored. Rauperaha, after peace was restored, exerted himself greatly in forwarding the building of a church, which was done entirely by the Maoris. It is only of timber, but it is the largest building they have ever yet erected, being 300 feet long, and in the chuchyard attached to it Rauperaha was buried in 1849 with due Christian rites. His son is still the acknowledged head of the tribe, and is very much respected and looking like a clergyman. The population in 1850 was 604. Petre is a small but flourishing little place on the west coast of New Ulster, and on the right bank of the Wanganui River, 4 miles from its mouth, and about 100 miles from Wellington. Its population in 1848 was 432, of whom 276 were males and 156 females. It consists of about 40 houses, a church, a school, a post-office, and a small jail, all of wood. It was founded in 1842, soon after the first settlement. It is a village of much great local reputation for its hams and bacon. In 1847 however an unfortunate quarrel with the natives of the valley led to the destruction of the place. On peace being restored the colonists returned, and resumed their occupation of the land, and a church and school is now stationed at Petre. Putikiraua is a native village on the Wanganui, opposite to the town of Petre. It has about 3,000 inhabitants, but the whole number in the district probably amounts to 5,000. The inhabitants have now applied themselves sedulously to industrial pursuits, bringing their produce down the Wanganui in canoes, which they manage with great dexterity down the rapids, with a cargo sometimes weighing a ton, and contrive even to ascend them with their canoes light. Waikanae is a native village about 20 miles S. from Otaki, at the mouth of a small river of the same name. It is in the same style as Petre, and was founded in 1842; but a fresh outbreak has come up an ordinary—an unlimited dinner for a shilling; but as his fellow-citizens prepared themselves for it by fasting the whole of the previous day he found it unprofitable, and restricted the meal to two pounds of pork, two pounds of potatoes, sauce and half a gallon of beer, the latter alone resembling a huge barn, says Colonel Mundy ('Our Antipodes')—and the military coast-road from Wellington passes through it. Wanganui Bay (celebrated as being the scene of the massacre of the crew of the Boyd in 1808) is about 200 miles N. from the Bay of Islands in New Ulter. The entrance to the harbour is narrow, between steep rocks of great height; but the water is deep and the inner harbour is very spacious, and sheltered from all winds. The country around is mountainous, and not adapted for cultivation; but the hills are covered with timber, among which the Kauri pine was particularly abundant, but has been much thinned. A few Europeans are settled here, and there is a native village of about 3,000 persons, with Protestant and Catholic missionaries, and a church and school. Otaki. The name the late Lord Dundas, one of the principal proprietors of Shetland, took the title of Earl of Zetland when elevated to that rank in the peerage in 1838. The name is also retained in the title of the lord-lieutenant and sheriff of Orkney and Shetland. Zetland Islands, also occasionally applied to them. Shetland was called by the Norwegian colonists Hjaltland and Healtland, which became changes into Shetland and Zetland. The name the late Lord Dundas, one of the principal proprietors of Shetland, took the title of Earl of Zetland when elevated to that rank in the peerage in 1838. The name is also retained in the title of the lord-lieutenant and sheriff of Orkney and Shetland. Zetland Islands, also occasionally applied to them. Shetland was called by the Norwegian colonists Hjaltland and Healtland, which became changes into Shetland and Zetland. The name the late Lord Dundas, one of the principal proprietors of Shetland, took the title of Earl of Zetland when elevated to that rank in the peerage in 1838. The name is also retained in the title of the lord-lieutenant and sheriff of Orkney and Shetland. ZEUS, a genius of Fiesha belonging to the family Scombridae. The Boar-Fish of English writers is referred by Jenyns and others to this genius, but Cuvier, Lacépée, and Harrell, refer it to Capros. (Capros.) ZEBRETTE, a sandpiper, is by the ancients called Lapidoptera. The male antennae are furnished at the base with a double row of teeth, which are terminated by a thread: those of the female are single at the base. Z. ZecCEI, the Wood-Leopard, is a rare species, of a white color, with black and red steel-blue spots. The larvae are found in the interior of decaying trees. ZHUKOVSKY, VASILY ANDREEVICH, a Russian poet of the first order of eminence, was born at the village of Mihanskie in the province of Moscovia, in the year 1788, and studied at the university of St.Petersburg. He was chiefly brought up by his mother, grandmother, and aunt, in a household which contained nine girls and three young women, and in which he was the only boy. At school he had at first the reputation of being lazy and very averse to dry studies, while at home his good looks and good nature procured him admittance into the company of the girls into a troop of actors, and at an early age set up a play of his own composition, 'Camillus, or Rome Preserved,' in which he acted the part of the hero with great applause from the neighbours who were invited to the performance. The work was, however, a failure, and having been given him for a theme at school, he produced an exercise of such excellence that it has been inserted as a classical piece in several Russian compilations of the nature of school-books. At this time he began to appear in print by contributing to one of the Moscow periodicals under the signature of the 'Hermit of the Mountain;' and it was remarked, that while gay and lively in society, he was disposed in composition to be mild and meditative. The same appearance is observable for some years between different towns in winter and his native village in summer: and while at the schools of Tula and Moscow he gradually won his way into notice and
distinction by proficiency in study, at the village of Mishenery, which was picturesquely situated on the banks of the Oka, he cultivated his talents for poetry, music, and drawing, for all of which he had a natural gift.

It was at a house within sight of the church and church-yard of a nearby village, a number of which he signed his name,  

'Elegy in a Country Churchyard,' the first production of his pen which made an impression on the public. Gray's  

'Elegy' is at this moment the most universally known and universally popular piece of poetry in existence. Bowring, in his edition, says that he had seen more than one hundred and fifty different versions, and among them Zhukovsky's is undoubtedly one of the best. This fortunate translation, which was published in 1802, was, like Moore's 'Anacreon,' the foundation of a fame which extended throughout the world, and even before it appeared in the 'Viestnik Evropeii, or European Inteligence, 

then the leading periodical of Russia, of which Karamzin, its most popular author, was at the time the editor, and it introduced him at once to the friendship of Rostopchin and Dostoevsky, and in position amid the best literary society of Moscow. A few years later, in 1808 and 1809, Zhukovsky became himself the editor of the same periodical, but he soon relinquished the employment, thenceforward devoting himself to a literary career. In the war of 1812, both Karamzin and Zhukovsky were anxious to bear arms, but the bodily infirmities of Karamzin would not allow him to sit on horseback, and Zhukovsky took leave of him at Moscow at the house of Count Rostopchin, and then resigned, to be joined, to his name, to the army. As a lieutenant of the Moscow volunteers, Zhukovsky fought at the great battle of Borodino, and he took an effective part in the subsequent memorable campaign, both as a bard and a soldier. It was in the former capacity, that the most distinguished of his productions, 'Minstrel in the Russian Camp,' a series of songs on the war, created unbounded enthusiasm among the soldiery, were struck off at a military printing-press, and circulated and sung throughout the army. The poet, however, unaccountably took the part of a man who was, by fever, and obliged to quit the army early in 1813. The Empress mother, Maria Theodorovna, who had been delighted with his poems, was anxious to see and reward the 'Minstrel;' a special audience of the Tsar was granted to herself, and Zhukovsky, who had been decorated with the order of St. Anne for his military services, received from the Emperor Alexander a pension for life of 4,000 rubles. For some years afterwards his time was spent at St. Petersburg, in the employment of imperial favour, of great success in society, and till the rise of the Russian Byron, Pushkin, of the reputation of being the first poet of Russia.

He most poetic productions in this his most productive period were ballads, the first and best of which was the 'Minstrel,' a poem written in the imitation of Pushkin, and which he was the first to introduce into Russian literature. His first poem of the class, 'Zundmilla,' an imitation of Bürger's 'Lenore,' startled the Russian public into a burst of enthusiastic admiration. He afterwards treated the same subject with variations in a poem entitled 'Svietlana,' which is still considered his masterpiece, and finally he translated 'Lenore' itself simply from the German into Russian. Almost all his subsequent ballads are founded on foreign originals, and contrast what some of the best of them do, with the popularity of England, France, and Germany, in looking through the ballads of Zhukovsky, is continually meeting with old faces and old favourites. From Southerly alone, the Russian poet borrowed, without the mention of Southerly, 'A Conversation,' 'The Turnpike,' 'The Rattlesnake,' 'The Muleteer,' 'The Frenchman and Jew,' 'The Marabout of Morocco,' 'Rudiger,' 'The Old Woman of Berkeley,' and 'Lord William,' the title of the last of which he altered to 'Varwik,' the nearest approach which the Russian alphabet allows to the English 'Warwick.' Still more strangely, while the ballads of Smolthom bowers are acknowledged to be taken from Walter Scott, a tolerably close version of the condemnation of Constance, from the second canto of 'Marion' is presented to the reader of Zhukovsky's works, as 'The Trial Underground, a fragment of an unfinished poem.' This mode of proceeding is not confined to Zhukovsky, and

seem to be in accordance with the Russian code of literary ethics: as, though the native critics must be aware of the fact, we have never seen it mentioned with blame. How apt it is to mislead, may be shown from the example of Merimee, who, in his life of the false Demetrius, speaks of the place where the Polabin Bank had been built, as having to be drawn from the Russian Byron, Pushkin, the very curious compliment paid to it in the ballad of 'The Three Sons of Bodrya,' quite unaware that the ballad in question has been transferred without acknowledgment from the Polabin bank in Breslau.

Leaving their origin out of view, the ballads of Zhukovsky are beautiful specimens of animated narrative, and in his own poem of 'Svietlana' (which has been translated into English by Bowring) there is a power and force of what is called the immediate effect, until it is equalled in any language. In his first romantic poem, 'Russian and Ljudmilla,' Pushkin showed a similar power, and Zhukovsky sent a present of his works to him with the inscription, 'From the conquered teacher to his conquering pupil.' They became intimate friends, and around them they were grouped for several years all the most eminent literary society of St. Petersburg, which was in the habit of meeting at Zhukovsky's house. All shreds of opinion were repressed, and Pushkin's name is given to a contribution to 'The Polar Star,' edited by Bestuzhev and Rulilyev, who afterwards perished on the gallowas and in exile for their-sorropby against the Emperor Nicolas. Zhukovsky became more and more connected with the circle of Pushkin, and when Nicolas quarrelled with a Prussian princess, he was selected to teach her the Russian language; and when Nicolas became emperor, and the offering of the marriage, the hereditary prince, was of an age to require a preceptor, Zhukovsky was appointed. A change of residence, from the active pursuit of literature, but enabled him in various ways to set efficiently for the benefit of his literary brethren. It was by the influence of Zhukovsky that Herzen was allowed to return from exile, and that Mikhailovich's 'Memoirs' were at last obtained with permission to quit Russia, which he had entered as a captive. He too had probably a hand in obtaining a pension for Pushkin's widow after the decease of her husband, and the elevation of Pushkin to the new rank of a poet. Zhukovsky, with his Cabinet, visited the vast empire which was to fall under his sceptre, Zhukovsky acted as his Mentor, and he also accompanied him in his visit to Germany, Italy, and England. The poet had made tours in Germany and Italy before, but to England he had not been invited. Zhukovsky's poems had been translated by Bowring, and noticed by Byron, it is probable that the 'Minstrel in the Russian camp' was recognised by few under the disguise of the French appellation on his name—'M. de Jukoffsky.' On his visit to the British Museum however, one of the assistant-librarians, who was a student of Russian literature, had the satisfaction of showing him an edition of his works which had just been added to the national library. Shortly after the prince's return to Russia, his creations in poetry, Zhukovsky's health had for some time been indifferent, and he transferred his residence to Germany, a country of which it is said he was 'passionately fond, to have the benefit of the waters.' He had always been a lover of health and recreation, and had been attained his fifty-ninth year and was still a beaholer. The Hereditary Prince in his European tour had been in search of a wife, and on the 28th of April 1841 he married the present Empress of Russia, the daughter of the grand-duke of Oldenburg, who was a pupil's example. On the 21st of May 1841, at a little Russian chapel on a hill near Canstadt, which was erected over the remains of a Russian princess who had been queen of Wurttemburg, he was married to a beautiful girl of the name of Reutern, and was in the summer of the same year, at the close of one of the Baltic provinces. Six years afterwards he wrote to a friend in raptures at the domestic happiness which had fallen to his portion. He chiefly passed his time at a retreat in the neighbourhood of Dusseldorf, and amused himself with translating into Russian poems by...
Ferdinand and Homer. Two children, both boys, were the offspring of the marriage, and their delight was very great, which he thought his life might be prolonged to his eightieth year to see completed. Neither this wish nor that of revisiting Russia was fulfilled. On the 12th of April 1852, Zhukovsky was met and resigned, at Baden, in the bosom of his family. His remains were afterwards removed to his native country.

An edition of Zhukovsky's works which appeared at St. Petersburg in 1853-57, fills eight octavo volumes, and contains his most of his poems. One of the eleven volumes consists of prose, the remainder are all either original or translated poetry. Among the prose the pamphlet is generally given to a tale entitled 'Marina Roschas' (Mary's Grove), the name of a favourite resort of the inhabitants of Moscow, which ever since the tale appeared has been regarded in the light of a classic spot. There are some fragments of a diary kept by Zhukovsky on his tours in Italy and Germany, which are singularly vivid, but nothing apparent has been said of his common material for packing, and for stuffing ottoger's cushions; it has also been used medicinally as a poultice.

ZOUA, River. [AFRICA, S. 2.] ZSCHOKKE, JOHANN HEINRICH DANIEL, was born at Magdeburg in Prussia on May 29, 1771, and received the earlier part of his education in the Kloster-shule and in the gymnasiurn of that town. When only seventeen he quitted his school and family, and became play-writer to a troop of strolling-players. In a short time, with consummate skill, he had become a theatrical manager, and was sent to the university of Frankfurt-on-the-Oder, where, without any settled plan, he studied philosophy, theology, the fine arts, history, and finance. In 1792 he commenced private teaching in Frankfurt, but with little success; and he employed most of his time in writing stories. In 1793 he published 'his 'Abillino, the Bandit' (of which the story was borrowed by Monk Lewis for his 'Bravo of Venice'), and 'Julius von Sasson,' produced at this period, were favourably received. In 1794 he wrote the first part of 'Atlas, a poetick edict respecting religion, and therefore when in 1796, he applied for a professorship it was refused. He then left Frankfurt, travelled about Germany and France, and at length settled at Reichenau in the Graubunden, where, in conjunction with Eckermeyer, he established a school for boys, which was so well conducted that the canton presented him with its freedom as a burgher, and he evinced his gratitude by writing his 'Geschihte des Freistaats der drei Bünde in Rhaetien' (History of the Free State of the Three Bunds in Raetien), which was published in 1790. This is an account of the early associations of the canton for the establishment of its liberties, and was the precursor of several other works on the history of Switzerland.

In that year however the Canton of Graubunden declined to join the Helvetic republic, and was sent to the university on the French influence; Zschokke was in favour of the union; he became unpopular, and his school was the sacrifice. Austrian troops entered the canton, and Zschokke withdrew to Aarau, where the central government of the canton invited him to establish a school for the training of talents, and his political opinions, procured him employment under the government. He was made chief of the department of education, and was sent in the capacity of a fully empowered commissioner to the commission for the affairs of Unterwalden, the suffering from the devastation of the foreign enemy and the effects of party violence, where he acted as a true benefactor and a restorer of peace. A memorial of this remarkable period is given in his 'Historischen Denkwürdigkeiten der Schweizische Staatsm.-würmung.' (Historical Memoirs of the Swiss Revolution). His commission was subsequently extended over the cantons of Uri, Schwyz, and Zug, and his appeals for the help of the miserable sufferers remain in proof of his skill in the years of eleventh the year 1801, to the commission for the affairs of Unterwalden, the suffering from the devastation of the foreign enemy and the effects of party violence, where he acted as a true benefactor and a restorer of peace.

ZOARCE, Grau Wrecks, a natural order of Endogenous Marine Plants, resembling sea-weeds, and living among them. The species have grassy thin leaves, which are usually in a mass; the flowers are absolutely naked, or surrounded by three scales. If we are to find anywhere a positive interrelation of flowering with flowerless plants, it is here, where, with waked flowers but distinct sexes, the pollen is in a condition that may be brought to the requisite form and position of the little, and totally different from all that is known of other flowering plants. The habit too is quite that of sea-weeds. The manner in which fertilisation takes place among these plants is unknown. The bottom of the tube is thickened, and they occur in shallow waters extending to the Mediterranean, the Indian Ocean, and the coasts of Arabia. One species only is seen on the shores of Australia, and another in the West Indies.
governor of Basel, where a commotion had arisen against the land-tax and tithes; he there threw himself into the midst of an armed assemblage of the people, and induced them to follow his advice and submit. When the central government at Bern, with the Landmaß Aloys Reding at its head, prepared in 1801 to restore the ruptured federalism of the union, Zschokke resigned his office, as he doubted whether the attempt could be successful then, and he retired to Biberstein in Aargau, to devote himself to his favourite studies. Much civil contention arose, and a civil war seemed inevitable, when in October 1802, Bonaparte offered his mediation, and by it the federal union of Switzerland was established in 1803. The modification brought Zschokke again into political activity. He was presented with the citizenship of Aargau, and nominated by the government in 1804 a member of the council of mines and forests. In the same year he commenced his popular "Schweizerboten" (Swiss Messenger), and in 1807 his "Miscellen für die neueste Weltkunde" (Miscellany of the most recent Events), which was continued without interruption till 1813; it displayed a happy choice of subjects, a richness of contents, a conscientious liberalism, and in general a strong and correct judgment. In 1813, when the Swiss after the downfall of Bonaparte, again wished to reconstitute their constitution, Zschokke exerted himself to maintain peace in Aargau, while he strenuously defended its independence against the claims of Bern. In 1829, in consequence of some imputations against him as editor of the "Schweizerboten," he resigned his offices of church and forest inspector, but retained those of member of the council, of the school directory, and president of the directorate of the school of education for artisans. In 1830 he was re-chosen a member of the church council, and he continued to exert himself actively and effectively in the promotion of education and all social reforms, though his time was now chiefly given to literary composition. With these duties and his literary works, which became extremely numerous, he continued to occupy himself until his death, which took place at Biberstein, on June 27, 1848. His published works are of very varied character. We have noticed some of his historical and political productions, but in this class the most valuable are his "Geschichte des Bayerischen Volks und seiner Fürsten" (History of the Bavarian People and their Princes), 1813-18; and "Das Schweizerlandes Geschichte für das Schweizervolk" (History of Switzerland for the Swiss People), 1822; which are highly esteemed, have been frequently reprinted, and are distinguished by a lucidity of arrangement, clearness of perception, a keen insight into character, and warmth and passion of expression; com. novels and tales of all other classes in number. Among the best are his "Adventures of a New Year's Night," which was translated into "Blackwood's Magazine," "Jonathan Frook," a serio-comic novel, "The Dead Guest," and "The Goldmaker's Village." His merits are a correct delineation of the nicer shades of character, a naturally simple pathos, a happy exposition of some of the weak points of our social institutions, a considerable amount of humour, and a constant maintenance of good principles and feelings. Some of these novels, like the "Cottagers of Glenburnie," aim at effecting the removal of social evils, national prejudices, or injurious customs, such as "Die Brantwincest" (The Brandy Pest); he is frequently tedious, and his plots are improbable, and the least happy of his attempts are of the historical class. His poetry seldom rises beyond mediocrity, nor are his dramatic attempts of a high character. He had much knowledge of a kind fitting him for his office of inspector of forests, and was acquainted with geology, particularly in reference to the country in which he resided, as is shown in his "Gebirgsförster" and "Die Alpenwälter." By far the most popular of his works was his "Stunden der Andacht" (Hours of Devotion), which was first published as a Sunday periodical, and which has gone through forty editions. It is one of the most complete expositions of modern rationalism, but its want of orthodoxy was held to be compensated by its fervid eloquence, and its zealous inculcation of every practical duty in all ranks. This work was not known to be his till the appearance of his "Selbstacht," a sort of autobiography of a somewhat singular character, which has been translated into English. He published a collected edition of his historical writings, in 1830, in 16 volumes, and a selection of his novels and poems in 10 volumes, in 1847; but an edition of his collected works, in 1829, occupied 40 volumes. Many of his works have been translated into French, and in English we have his "Gol- dental," a tale; "Der Goldmachersordor:" "Love's Strategem," and other tales; "The History of Switzerland," 1 volume of select essays; and the "Stunden der Andacht," under the title of "Hours of Meditation and Reflection."
